CALLOW SCREENS IN THE CONCENTRATOR OF THE STEPTOE VALLEY SMELTING AND MINING COMPANY, McQUILL, NEVADA.

We have received orders for Callow Screens from this Company as follows:

April 20, 1907—2 Duplex Machines
June 5, 1907—6 Duplex Machines
August 20, 1907—6 Duplex Machines
March 21, 1908—1 Duplex Machine
May 24, 1908—15 Duplex Machines

OR A TOTAL OF 30 DUPLEX MACHINES ON 5 ORDERS.

The Utah Mining Machinery & Supply Company

J. E. GALIGHTHER, MANAGER.

Salt Lake City, Utah, U. S. A.
MR. MILL MAN

THE MODEL C CARD CONCENTRATOR SAVES THE FINE MINERAL AND IS DOING WHAT YOU ARE TRYING TO MAKE SOME OTHER MACHINE DO.

Facts are all we ask you to consider

Don't you know the problem is a hard one? Don't you know you are losing values? Don't you know the experiment is costing you good round dollars? Don't you know the Card Concentrator can save these values at a less cost than you are now losing per month? The Card will make separations of several minerals at one operation, dependent only on their specific gravity. By the adoption of broad, flat springs, set at right angles to the bed frame, on which the body of tables swings, we have succeeded in reducing the wear and maintenance to practically nothing—at the same time reducing cost of operation. Can't you see how simple the operation is? Just an easy swinging motion.

No wear and necessarily no repair

Yet the saving is complete. Why not investigate? Let us pay the postage to you on our complete descriptive catalog. Your name on a postal will bring the desired results. Write today.

MEXICAN domestic difficulties must not be judged too hastily from press dispatches. News from the border is always generated at high tension; the voltage is out of proportion to the amplitude. The Mexican Government is no more likely to fall to pieces than that of the United States at the time of the Chicago riots. One needs to be abroad and read the dispatches from home at such a time to appreciate what allowance must be made for journalistic exaggeration. It is hard for the average news-gatherer to damage the potentialities of a thrilling story by giving all the details. From the most reliable data now available, the Mexican flurry seems to be a result of hard times, lack of employment, and physical suffering from actual want. A comprehensible sentiment has led even to a demand that foreigners be dismissed from the State-controlled railways to make room for starving Mexicans. There may be more logic than revolution in the recent disorders. Until more sober information arrives, it is best to suspend judgment. At any rate, the authorities seem to have the situation well in hand, and there is no danger in the Republic for the man who minds his own business as he should.

Grover Cleveland.

GROVER CLEVELAND, ex-President of the United States, passed away at his home in Princeton, New Jersey, on June 24. The centre of violent political controversy while at the height of his public career, he became the repository of a nation’s respect and confidence when he laid aside the cares of state. For sane balance of work and recreation, for the adornments of culture, and by manly criticism and suggestion untinted by party bias, he has set an example worthy of emulation by all the citizens of a republic. Mr. Cleveland was not simply greater than party; he not only did not dominate a faction for his political aggrandizement; he practically dispensed with party, and rose to power on the people’s favor, despite the politicians. He distinguished himself above all others in giving practical effect to civil service reform. While personally desiring the annexation of Hawaii, he withdrew from the Senate the treaty drafted for that purpose, because the de facto government offering annexation owed its existence to an armed invasion by forces of the United States. His Venezuelan message, so often referred to as an example of jingoism, in the light of subsequent events is seen to have been based upon motives of justice similar to those which prevented his acquiescence in dishonorable annexation schemes. That Anglophobia had no part in his famouss act soon became clear to England also, when Mr. Cleveland, through his Secretary of State, negotiated a
general arbitration treaty on the broadest lines with Sir Julian Paunee, the British Ambassador. The highest tribute ever paid to his capability and honesty consisted in the abatement of anxiety over the probable outcome of the Equitable Life Assurance Society's troubles when he was named as one of its trustees. Public confidence was instantly restored, and a calmness which threatened to shake the foundations of our institutions of credit, was averted. Such was the power of one simple citizen in whom the people trusted.

The Curse of Potosí.

The genially scrupulous Diedrich Knickerbocker began the History of New York with the creation of Adam in the Garden of Eden. Thus all the circumstances leading to the invasion of the Manhattan solitude by the Hon. Peter Stuyvesant were presented in such array of logical sequence as to compel conviction of its inevitability. In like playful spirit, and with a sly wink at the necessitarians such as Washington Irving might have tossed at the picture of Jonathan Edwards on his study-wall, Mr. J. H. Curle demonstrates, as appears in a letter printed elsewhere in this issue, that the accession of Theodore Roosevelt to the Presidency of the United States is traceable as a direct consequence from the discovery of Peru by Francisco Pizarro in 1528, and the opening of the wonderful treasure-mountain of Potosí in 1545. Quaint though this suggestion be, it is worth while to fall into such reflective mood in the presence of stupendous facts of nature which have profoundly influenced the destinies of men and nations. Mr. Curle, confronting the great metalliferous cerro in Bolivia, sees a chain of growth through industry quickened by the silver stream that poured from this wonderful mountain into Spain and thence to the manufacturing cities of Europe. Nothing like Potosí has ever been witnessed in the world before or since. An ancient Spanish chronicler, attempting to convey an impression of the vastness of this silver treasure, represented the mountain as a cone with a vent on top like an ant-hill, with cargo-men as thick as ants crowding in and out, and others digging the silver from the cavernous interior.

The effect of Potosí did indeed extend to the colonies of England in North America. If Spain had reached a higher state of development before this wealth was poured into her lap she might have employed it to build up industry at home. Instead she acted the part of a spendthrift, buying what she should have produced herself. Thus unconsciously she gave aid and comfort to her enemies, and hastened the destruction of her unstable power. Mr. Curle does not repeat the error of the late Lord Salisbury, who called Spain a decadent nation. With more correct appreciation of the truth he says, "the Spanish people during this period could not have been the greatest people in the world—they were only the richest." He might have added that they were at once the richest and the least prosperous. It was a curious destiny that kept Spain for seven hundred years the out-post guard of Europe against the Saracen, only to quench her victorious spirit in a flood of unearned riches from the New World, before opportunity had come for developing a self-conscious national life through those well-knit energies which result from normal industry and economic struggle. There has run through the world a Gallie spirit of culture, an Anglo-Saxon spirit of development of natural resources, a Germanic spirit of scientific enquiry, but from Spain have come chiefly melody and romance, the beautiful things of national childhood. The canción sung to the plaintive chords of the guitar, the fables of El Dorado and the Fortunate Isles, the daring of unknown dangers with ships burned behind, the clash of arms, and miraculous victories—these come to mind when Spain is mentioned, while France suggests the loom and the atelier, England the smithy, and Germany the laboratory. Charles the Third, who came so near being Charles the reformer, deliberately undertook to dam up the silver river from Potosí in its course by a tariff-wall around his beloved Spain. But the way to make a protective-tariff tax the foreigner had not been revealed to the Spanish statesman. The people were recalcitrant. The dam was too high for its width of base, and it overturned. Not until Spain lost her colonies did reason and prudence change the ruinous policies derived from the prodigal days when the mines of Potosí emasculated the moral force of her people. The youthful dream of fortuitous wealth could not be dissipated while colonies remained to be exploited. The exchequer was always exhausted, and an impending mountain of debts ever threatened destruction. Whether Premier Praxedes Sagasta, foreseeing the possibility of deliverance, craftily precipitated the Spanish-American war or not, certain it is he was not averse to it, and he welcomed its inevitable consequences. After the first shock was over, the wholesome reaction came. The liberal minister of finance, Señor José Echegaray, for the first time in more than a century was able to display to the Cortes a surplus instead of a deficit, and for the past five years the national finances have been conducted on a similarly happy basis, while private industry, outside of agriculture, has been thriving at a rapid rate as compared with conditions in the past. The effort to absorb the industrious Hollander, so as to keep more of the silver of Potosí at home, proved futile. It only made more reformers and fighters, and helped to build up prosperous Puritan New England, and pave the way for Theodore Roosevelt—according to Mr. Curle. Charles III could not dam the stream at the frontier; the Duke of Alva could not hold the Lowlauds, whither so large a part of the stream was determinedly flowing. But Roosevelt on San Juan hill could help to liberate Spain from the lingering remnant of the curse of Potosí. Not even the mining industry can thrive on extravagant bonanzas. As recently seen at Goldfield, high-grade ore leads to "high-grading", to wide-spread moral perversion, to waste and dissipation. Moderate reward for intelligent effort is the foundation of true success. The mining world is no exception to the rule, and Potosí, hindering the development of a strong people for centuries, is a striking case in point.
Mining Claims on Forest Reserves.

MINING in its relation to the national forest reserves is coming to be a question of large importance. In our last issue we published a memorial from Montana protesting against the narrow construction which the forest reserve officials have placed on our mining laws, and the attitude of apparent hostility manifested toward mining interests situated within these reserves. It is not Montana alone which has cause for protest. In most of the mining counties of California like grievances exist. We appreciate that some of the criticism emanates from those who have found it no longer possible to pervert the mining laws to the acquisition of lands for purposes foreign to the legitimate extraction of mineral from the soil, but, on the other hand, specific instances have come to our knowledge which would seem to indicate that certain of the forest reserve officials were becoming over-zealous in their endeavor to establish records for themselves. Many of the rangers detailed to examine and report on the character of the land embraced within mineral applications have no proper qualifications for rendering fair and intelligent reports. They are innocent of practical experience in mining, and are often unable to find the claims. The special knowledge of a surveyor and of a mining engineer are required of the rangers in such cases, and through lack of such knowledge the claimant suffers. Recently, a ranger filed an adverse report because he was not certain as to the exact location of the boundaries of the claim in question, and, at the same time, admitted that he thought the land was probably mineral in character, but protested it "in order to be on the safe side." Under such circumstances the claimant is put to the expense, delay, and annoyance of a hearing because of an official's ignorance.

Another serious difficulty has arisen since the creation of forest reserves. In recent years the Land Department has been most rigorous in compelling conformity of placer claims to legal subdivisions of the land. The rule has frequently been forced to a ridiculous extreme. Even where the placer deposits are confined to comparatively narrow and limited territory along a stream-bed, the claimant has no alternative but to amend his location and embrace a contiguous territory which may have absolutely no value for mining purposes. Many cases have come to our attention where, after conforming their claims as required by the Land Department, the claimants find their application for patent protested by the forest service on the ground that the non-mineral territory which had been included under compulsion was declared more valuable for timber. They avoid Seylla only to be engulfed in Charybdis. A forest supervisor in the northern part of California says that the majority of the protests filed in his district have arisen through conflicts of this nature.

Another radical defect in the forest reserve system as applied to mining is that there is now no provision for acquiring a patent title to a mill-site in a forest reserve. As soon as the non-mineral character of the mill-site is established, the land comes within the operation of the forest reserve act, and it is impossible to acquire a fee-simple title to it. In this respect, the forest reserve act has nullified the mining laws. Often a mine operator can place his mill on his mining claim, but there are cases where the only suitable site is some distance away on non-mineral ground. While there is provision in the forest reserve regulations for leasing a site for milling purposes, this leaves an operator at the mercy of the forest officials, even as to the rental to be paid, and the tenure of his holding is a license such that no cautious investor would feel justified in expending a large sum of money to equip and maintain a plant which might have to be forfeited to the Government.

We are informed that the leaders of the forest reserve movement are not only opposed to the idea of allowing mill-site areas to be patented in forest reserves, but they feel that it was a mistake for the Federal Government to have ever adopted the policy of parting outright with its title to the mineral lands of the public domain. They are strongly in favor of a leasing system under which the paramount title would never be granted. Our Government started on the leasing system, following the precedent of England, and the result was so unsatisfactory that it led President Polk, in his message to the Congress in 1845, to say: "The present system of managing the mineral lands of the United States is believed to be radically defective. More than a million acres of the public lands, supposed to contain lead and other minerals, have been reserved from sale, and numerous leases upon them have been granted to individuals upon a stipulated rent. The system of granting leases has proved to be not only unprofitable to the Government, but unsatisfactory to the citizens who have gone upon the lands." Congress thereupon ordered lead-bearing lands in Illinois and Arkansas to be exposed to public sale, as were other public lands. Similar Congressional action was taken later with reference to mineral lands in Michigan. Any radical change in our mining system, whether theoretically an improvement on the existing laws or not, will do vast immediate harm in unsettling conditions and in retarding steady growth. It would have an equally disastrous effect on the mining industry as would a radical change in our monetary and banking laws upon the financial world.

We feel certain that the forest reserve officials have no desire to cripple the mining industry. They cannot fail to recognize that the exploitation of mines is endangered by elements of uncertainty, at best, and that the development of our mineral resources needs every encouragement the Government can extend. The forest reserve system is of tremendous importance to the nation. It has already accomplished great good. But danger lies in its very greatness and power. Abuses are likely to spring up without the intention or knowledge of those in control. In writing the foregoing, we feel that we have pointed out errors in the administration of the forest reserves that deserve criticism. Those in authority have announced their desire to remedy defects, and we believe that protests such as that from Montana will assist in bringing about a harmonious application of the mining and the forest reserve statutes.
Personal.

Mark L. Requa is at Goldfield.
Howard D. Smith has gone to Lake Tahoe.
W. H. Stayer has returned to Freeport, Illinois.
Claude E. Jamison, of Los Angeles, is visiting San Francisco.

Hubert H. Hall is with the Yukon Gold Mining Co., at Dawson.

Edwin J. Collins has returned to Tonopah, from San Francisco.

Frank H. Probert has returned to Los Angeles from Pata-
san, Arizona.

Frank Bailey is superintendent of the Columbia mine, at Sumpter, Oregon.

L. K. Kennedy has returned to San Francisco from Green-
water, California.

Robert T. Hill of New York is in Nevada and will shortly
visit San Francisco.

W. P. Lasie is in charge of the Alaska-Juneau mine, in
Silver Bow basin, Alaska.

J. Morgan Clements is on his way to New York after an
extended trip through the West.

Alfred Tilly has left Barranquilla, Colombia, S. A., and
will reside at Falmouth, England.

Edward C. Weatherly, who has been at Ouray, Colo., for
the past year, has returned to London.

John B. Fairish is at Guanaque, Durango, Mexico, and
will be in San Francisco about July 15.

Grant E. Davis has left Rawhide, and will open an office
as mining engineer at Manhattan, Nevada.

F. L. Bosqet has returned to San Francisco from a visit
to the Mónica mine, near Kirkland, Arizona.

E. J. N. Orr, formerly assayer for the Alaska-Treadwell
Mining Co., is now at Nevada City, California.

W. L. Cole, of the Mountain Copper Co., has gone to
British Columbia, and will later visit Butte, Montana.

Roy N. Bishop succeeds Arthur H. Brown as general man-
ager of the Trinity Copper Co., of Kennett, California.

William C. Green left from San Francisco on July 2
for Yokohama, from where he will go to St. Petersburg.

W. L. Saunders, president of the Interboll-Rand Co.,
has been in Denver attending the convention of the Civil
Engineers.

Byron E. James, until recently in charge of the Mining
Department, University of Idaho, leaves this week for Du-
rango, Mexico.

Frank Elmore has recently been in Melbourne, Australia,
after a visit to Broken Hill. He will return to London by
way of Vancouver.

Pope Yeaman has been re-appointed general manager
for the Nevada Consolidated Copper Company and the Blythe
Valley Smelting Co., at Ely, Nevada.

R. R. Horner, formerly with the Consolidated Gold
Fields, Ltd., of South Africa, has opened an office as a min-
ing engineer at 704 Peyton Bldg., Spokane, Washington.

John G. Kirchen has been appointed manager of the
Montgomery Shoshone Consolidated, at Goldfield. Mr. Kir-
chen is also acting as manager of the Tomopah Extension.

DIVIDENDS.

On July 3 the Buick Hill & Sullivan Mining & Concen-
trating Co., paid dividend No. 136, of $75,000. This makes
the amount of dividends paid since January 1, $499,000, and
the total to date, $10,299,000.

Geo. L. Hunt, of the Reno Iron Works Co., has re-
turned from Butte, Montana, and reports having received
an order for a large dredge from the British Butte Mining
Co., to operate on the ancient channel recently proved at
Rocker, four miles west of Butte.

ENGINEERING SOCIETIES.

During the past week five of the national engineering
societies held their annual conventions. The American So-
ciety of Mechanical Engineers and the Society for the
Promotion of Engineering Education held a joint meeting at
Detroit, Mich. The American Society for Testing Materials
and the American Railway Mechanical Association each
held its annual meeting at Atlantic City, N. J. The
American Society of Civil Engineers held its convention at
Denver, and the American Institute of Electrical Engineers,
their annual meeting at Atlantic City the first of this week.
General Mining News.

ARIZONA.

COCHISE COUNTY.

The No. 2 furnace of the Copper Queen is being overhauled and remodeled. The reverberatory furnace has been started and it is intended to keep it in commission from now on.

GILA COUNTY.

The Superior & Boston has recently started sinking a 1000-ft. three-compartment shaft on its property, 3 miles north of Globe. It is announced that heavy hoisting machinery and a compressor will soon be ordered, and that the railroad of the Arizona Commercial will be extended to the new shaft of the Superior & Boston. — It is reported that the Miami Copper Co., seven miles southwest of Globe, will install a concentrating plant some time this year. The Red Springs shaft is 700 ft. deep and a new level is to be started at the 670-ft. point.

SANTA CRUZ COUNTY.

It is reported that the United States Smelting & Refining Co. is considering the purchase of the Mansfield copper property, near Patagonia. — A hoist and hoist have recently been taken to the Red Cloud group of claims and will be used in sinking a new shaft.

YAVAPAI COUNTY.

A new double-compartment shaft is being sunk on the Emporia, seven miles south of Prescott. This mine was recently sold to a New York syndicate. A new hoisting plant will be installed and the shaft carried down to a depth of at least 400 ft. before any extensive lateral work is commenced. — The Mount Elliott Con. Mines Co, at Chaparral, shipped two cars of concentrate last month, and expect to maintain the same output in the future. The bullion shipments are also satisfactory. The company will resume sinking in the 400-ft. shaft during July, and will install a 10-drill compressor. It is rumored that the 10-stamp mill will be replaced by a modern 40-stamp plant some time next fall.

CALIFORNIA.

AMADOR COUNTY.

The Bay State mine, near Plymouth, has started a small force of men repairing the hoist, which was recently destroyed by fire. When the repairs are made the mine will again be worked.

CALAVERAS COUNTY.

A rich strike was made last week in the Cross shaft of the Ulrich. It is claimed that 17 sacks, worth more than $100,000, were taken out. — The Green Mountain, the Green Mountain Ex., and the Chili Gulch placer mines, all near Nokelsunne Hill, have been sold to T. C. Huxley, of Oakland. A new company is being formed, which will build a dredge and also develop the two deep channels which pass through the property.

NEVADA COUNTY.

(Special Correspondence). — At the Central shaft sinking has been suspended and the shaft is being put in shape for the cutting of stations at the 5000 and $400-ft. levels. An electric pump will be installed near the 5000-ft. level to keep the lower levels free of water. Good ore has been developed at several points in the new workings. — The Conlan mine has been inspected by five of the largest stockholders. They favor the re-incorporation of the company, in the belief that such a course would enable the owners to untangle the financial trouble and operate the mine. — The adit being driven at the Colina mine, to intercept the vein, is 125 ft. Three shafts are working. — H. S. Abbot is examining the Ethel mine in the interests of Goldfield mining men. A few men are working at the property. — Several parties of lessees are working in the Champion and Home mines. Good ore is being mined at several points.

All work has been suspended by the company.— Practically all the men working at the Brunswick mine have been laid off pending the settlement by the board of directors of the future working plan of the property. It is rumored that a new shaft will be sunk. — It is reported that Senator Nixon and George Winfield, of Nevada, will shortly visit the Grass Valley district with a view to the purchase of mining properties.

GRASS VALLEY, June 29.

PLACER COUNTY.

It is rumored that the Orpheum mine, near Auburn, will build a 10-stamp mill and work the property on a large scale. — The Blue Eyes, above the last Chance, has started up. — The Alpine mine, near Greenwood, is adding 10 stamps to its mill.

SIERRA COUNTY.

The Trinity Copper Co. has recently sold to the Bully Hill Smelting Co. about 700 tons of ore for use in the latter plant as a fluxing mixture. The ore was shipped from a storage bin of the Balaklais, which was filled before the close-down last October.

SIEGELMINE COUNTY.

Morrell & Rea have taken a bond on a group of mines near Mountain House, including the Brush Creek and the

Map of Arizona.

Ante Up. The Brush Creek has produced large quantities of bullion in the past, but owing to internal friction among the owners it has not been worked recently. It is believed that the new owners will work the mine on a large scale. This is the second property Morrell & Rea have recently purchased in this district, the first being the Tom Boy, near Forrest. — The Poker Flat gravel mine has started a shaft on the property belonging to the company of the same name at Poker Flat. The shaft will be sunk to bedrock and the gravel mined from drifts and cross-cuts.

SULPHURMINE COUNTY.

The six-table slime plant erected by P. H. Craven of Spokane, Wash., at Shawmut, for the Eagle-Shawmut Mining Co., commenced operations last week. — The Lion Gold Mining Co. has been granted an additional month in which to resume operations under its bond on the 14a Klein mine, in Yorktown guich. — The new Omega mill has been running since the latter part of last week. The plant has 10 stamps and is electrically operated throughout.
COLORADO.

CLEAR CREEK COUNTY.

(Special Correspondence) — A rich strike has been made on the Pilz property, in East Arkansas. In extending the west drift on the Pilz vein a streak of heavy galena has been exposed that is from 10 to 20 in. wide. The ground has been opened for 15 ft. and the shoot has proved to be continuous. The ore assays 55% lead, from 60 to 75 oz. silver, and 1/2 oz. gold per ton. — A rich strike has just been made in the Scooper adit, Democratic Mtn. A body of ore has been uncovered that is 18 in. wide and assays from 170 to 225 oz. silver per ton, and 25% lead. A fair tonnage is now being broken, and within the next few days stoping will be started. The Scooper adit is an extension of the Sunburst, the adit now being advanced to cut under the Sunburst workings. When the objective is reached, a 330-ft. raise is to be driven. Galenaid in the adit. A force of men is being employed at the Mineral Chief mine, and shipments of both smelting and concentrating ore will be started in a few days. The aerial tramway has been completed and is now ready for the delivery of ore to the base of Democratic Mtn.

— Work has been resumed on the Faust group of claims, on Saxon Mtn. The adit is now in nearly 200 ft. and a streak of ore is being followed that is from 2 to 5 in. wide. A hydraulic washer has just been installed at the American Sisters mill, Columbian Mtn. Other improvements have been made at the 25-ton plant, such as the rearrangement of the machinery, and now the mill is running day and night. During the past week 50 tons of lead concentrates were marketed, that brought a return of 500 oz. silver, and 1 oz. gold per ton. The plant is being worked on material from the high-grade ore that was left on the former property, and a belt-conveyor has been erected in the hoisting of the ore. — Work has been resumed in driving the Raymond adit, Griffith Mtn. The bore is now in 875 ft. and another wire will be reached within the next few feet. Driving is in progress upon the vein, cut 825 ft. from the adit entrance, a body of 60 oz. silver-lead ore being followed as a wide. Stoping will be commenced in the adit shortly. Several pieces of machinery, including rolls, screens, and tables, arrived this week for the Crescent M. & L. Co. The equipment has been taken to the 10-ton mill below the dumps of the Mineral Chief mine, and as soon as it has been installed the plant will be run upon ores from the New Boston mine. — Work has been resumed at the Deanery copper property, near Georgetown. Three miles of the vein have been extended due to a lack of fuel. A new company is being organized and operations are to be carried forward on an extensive scale. — Work was resumed last week upon the Buffalo property, in the gulch between Alpine and Griffith Mtn. A cross-cut has been started to intersect the Buffalo vein at increased depth under the old workings. — Work is again to be put under way at the Lincoln property, Lincoln Mtn. The bond of $10,000 has been provided for, while a working capital has been subscribed. Driving will be started west on the Rambold vein, cut by the Market adit, and a raise is to be made to connect with the old shaft workings. The milling plant will soon be completed, or as soon as the kind of machinery to be installed has been decided upon.

Georgetown, June 27.

CLIFTON COUNTY.

A rich strike is reported from the Iowa Girl mine, in Moon gulch, near Rollinsville. The property is being developed by an adit which has been extended for a distance of about 200 ft., and in the face there is a large-sized stringer of concentrating ore through which are streaks of high-grade material. Placer of the ore have been roasted and show evidence of tellurium. Assays as high as $300 per ton have been obtained. — It is reported that the Pilnt mine, near the Perigo, has found ore in its 106-ft. level which assays more than $65 per ton in silver, and over $150 per ton in gold. — A new 200-ft. level to strike the same orebody. — The Siren G. M. & M. Co. is re-timbering its shaft at the head of Moon gulch. The company is to install a new gasoline hoisting plant and a shaft-house. — L. C. Todd, Central City, is in charge. — The Smuggler shaft, in Moon gulch, has been unwatered during the past week, and a drift has been resumed at the 100-ft. level. Stoping is also in progress in the adit, and a raise is being made to secure better ventilation. — It is reported that new capital has become interested in the Eureka property of John G. Striffer, of Tol- land, and that a new plant of machinery will be installed.

— The Rochester property, on Michigan hill in the Pine Creek district, is to be started at an early date. W. H. Bar- rick of Denver is interested in the Bunker group of claims, and improvements are being made at the new mill of the Square Deal M. & M. Co., near Gilpin, and the management expects to have the plant running at an early date. The mill uses the dry process and is especially designed to handle the ores of the Gettysburg group, in Lump gulch.

GUNNISON COUNTY.

The Camp Bird mine, at Bowerman, is sorting the shipping and milling ore, and last week shipped two cars of the former to Salida, and two are to follow this week. The mill is running steadily and will soon add 10 stamps to its present capacity. — The Augusta tram is operating and delivering the ore from the adit to the mill-site, nearly a mile distant and 1000 ft. lower. Encouraged by the success, surveys are now being made for an extension of four miles to the terminal of the railroad at Smith Anthracite.

LAKE COUNTY.

Arrangements are being made for extensive operations on the Crescentia shaft, on Rock hill. A controlling interest of the stock of the Rehate Mining Co., which owns the property, was sold during the week to Lou R. Johnston, of Denver, and associates, and it is announced that the new owners expect to enlarge the scope of their work. — A new boiler and engine have been put in at the Huckleberry shaft. When the property is unwatered the shipment of ore will be resumed.

SAN JUAN COUNTY.

The Anti-Periodic, on Galena Mtn., near Silverton, has resumed. — The small stamp-mill at Howardsville, erected by the Little Nations Co., has been pounding ore for the past week, and the management reports a good saving. The ore is carried from the mine, on King Solomon Mtn., to the mill by a mule pack train.

TELLER COUNTY.

The Consolidated Copper Creek Co., operating on the Del- monoico property, on Bull hill, will sink the shaft from the present level of 975 ft. down to the 1100-ft. point. A station will be cut at the 1000-ft. level. At that point, which corresponds to the 1000-ft. levels of both the Vindicator and Findley properties, an effort will be made to intersect the big shoots extending through both of these latter properties. — The Midget mine, near Cripple Creek, has had extensive operations after the close-down of the winter during which necessary repairs have been made to the compressor. — The Trinity mill, at Cripple Creek, is completed and will be put in commission early in July. The higher-grade ore is being shipped at the rate of about 600 tons per month. — The Maid of Erin, on the southwestern slope of Raven hill, made its first shipment in some time, last week. The ore came from the north side of the vein on the 400-ft. level, where Stoner & Agnew are leasing. — A steam-boist has been put in at the Baker & Co. lease on the Mountain Goat claim of the Coonanche Plume Gold Mining Co., and the lessees began hoisting ore last week. — A depth of 200 ft. has been attained in the new vertical shaft on the Ophir mine on Raven hill, and a cross-cut has been started to the main Ophir vein. — The Roanoke, on the west slope of Mineral hill, is again producing, after laying idle since 1904.
IDAHO.

IDAHO COUNTY.

Flint feet of gold and copper ore, averaging $29 per ton, has been worked in the Bunker Hill mine. The property, at Hagerman, is owned by J. H. Hargrove. The strike was made in an adit started two years ago, which cut the vein at a depth of about 65 ft. The property has not been worked for several months, and the owner was doing assessment work when the vein was struck. He is now planning to do extensive development work.

OWYHEE COUNTY.

The Wennersten Mining Co., Ltd., has been organized to work the mining property of the defunct Little Rose Co., on the west side of Florida Mtn., near Silver City. The company expects to sell most of its stock in London.

SHOSHONE COUNTY.

(Special Correspondence.)—One of the most important as well as the richest strikes ever known in the history of the county was made last week on the property of the Anchor Mining Co., at Burke. This strike was made at the bottom of a 35-ft. shaft, where one foot of carbonate ore and two feet of lead crystals were encountered. The carbonate ore assayed $2.22 per pound and the lead ore per ton. The crystallized lead assayed from 45 to 90% lead. The strike was made on the Diamond Hitch claim, between the Hecla and Mammoth mines. All the legal difficulties which had attended the development of the Rex mine are about to be settled, and the company's indebtedness of $10,000 is to be cleared off. Under the Francis lease, which was to terminate in 1899, the mine made more or less regular shipments to the smelter, and it is understood that several new and valuable orobodies were opened up during the development. A new syndicate has been formed to handle the affairs of the company, and it is probable that a resumption of work will take place in the near future.—A crew of miners has left for the Monitor mine, near Saltseet, Mont. These men are engaged by the Success Co., which has taken a bond on the property and has agreed to commence development work as soon as the preliminary preparations have been completed. The machinery at the mine will be re-modeled and a concrete foundation will be placed for the present hoist and engine. —Shiptons from the Morning mine, at Mullan, have commenced again, after a shut-down of several months. A full force of men has been put to work at the property, which is one of the biggest producers of the district.—P. F. Smith, of Wallace, has been appointed receiver for the affairs of the Amador mine, following the action commenced in the District Court here by Mrs. Mackinnon for the recovery of $25,000. The appointment was made by Judge E. E. Steele of Moscow. The receiver's bond has been fixed at $500, but up to the present time no action has been decided upon with regard to the affairs of the company. —The annual meeting of the stockholders of the Leslie Mining Co. was held this week at Wallace. Arrangements were made to drive an adit from the railroad track to tap the Leslie ore at 700 ft. greater depth than the present lower workings, and under the large and well-defined orebody exposed in the present working adit. The new work will be started in from 60 to 90 days, and it has been officially announced that it will cost the stockholders neither cash nor stock, although the arrangements have all been completed. This tunnel will be over 5000 ft. in length, and will give a total depth of about 1650 ft. It is intended to install some machinery at the spot where the adit will be started. This will consist of a 10-drill compressor, a drill-sharpeners, besides a new boarding and bunk-house and saw-mill. —Miners and equipment have been sent out to the Bullion property, near Saltseet, to get the machinery in shape for sinking. The completion of the raise which connects with the bottom of the shaft allows a continuation of the sinking on the vein. Including the raise, the shaft is now down 120 ft., and another 100 ft. of sinking will commence at once, when cross-cutting will begin.

Wallace, June 29.

KANSAS.

CHISWICK COUNTY.

(Special Correspondence.)—One of the largest sales of ores made in recent years was made at Galena this week by Lynch & Williams operating on the Lou Dillon lease. The ore was purchased by the St. Louis S. & R. Co., and consisted of 700,000 lb. of lead ore, estimated at $22,925. The company has been holding the ore since last year, and was offered $25.50 a thousand for it at one time, but refused the offer, thinking the lead prices would go still higher. —The Galena lead smelter has resumed operations after a shut-down of several weeks. The smelter could not obtain lead enough to operate and was forced to close. The amount on hand, together with the current purchases, will insure steady operation for some time. About 40 additional men were employed when the operations were resumed. —Frank Hunt and associates have begun the development of the Murphy land, west of Empire City. The property has not been actively mined, though drilling has been done upon it and sheet-ore found. The present company will drill to verify the old records, which state that sheet-ore was found at 250 ft. The development will mean much to this part of the camp, as the finding of sheet-ore would prove a valuable addition to the field already developed in the western portion of the district. —The concentrating works being erected by the Big Chief Co., at Baxter Springs, is nearing completion. The old Sloan mill was purchased and moved to the lease, where it has been remodeled and will now handle 200 tons of dirt per shift. Only a few mines in the Baxter Springs camp have continued to work steadily since the low ore prices. One of these, the M. K. & Y. plant, has just closed down indefinitely on account of the death of one of the members of the company. This mill was one of the best producers in the camp, and will mean a great loss to the weekly turn-in for that field.

Galena, June 26.

MICHIGAN.

A small double hoist used for some time last summer at the Empire shaft has been moved to the new No. 2 shaft of the Keweenaw Copper Co.'s Medora mine. —During the past week connection has again been established between the old Cliff mine and the South Cliff through the third level of the latter property. It has been over 50 years since the South Cliff was worked, and about 30 years since active mining work was stopped at the Cliff, known in its early days as the Pittsburg & Boston. Some intermittent tribute work has been carried on since that time, however. —The two shafts which the Ahmeek Mining Co. started last week will present some unique and novel engineering features. Both shafts will be sunk simultaneously, going down at an angle of 80° in the form of an inverted V, in this manner it will be possible to use a single rock and shaft house for both openings, saving in the first cost as well as the number of men necessary at the shaft, one crew being able to do the work of both shafts on the same headframe and take the dip of the shafts until they strike the ledge, when they will follow the dip of the mineralized formation. This plan of mining is similar to that begun some time ago at the Alvonex, and where it is being found entirely practical. —Tamarack plans to increase the size of the pumping plant on the shore of Lake Superior. The building will be 90 by 80 feet.

MISSOURI.

JASPER COUNTY.

(Special Correspondence.)—During the past week a number of mills in the district were closed, especially in the Webb City sheet-ground camp, where most of the ore pro-
duced is zinc-blende. The shut-down was caused by the low zinc prices, operators being unable to run the strictly zinc-producing mines at a profit. It is rumored throughout the district that an organized shut-down will be effected by the zinc producers by the first week in July unless the low price of zinc rises. Four of the large plants north of Wobbl City closed down last week, and these, together with the two plants burned, will materially affect the output of the camp. Almost all the mines in the district have been operated at increased expense this spring on account of the high water and the necessity of installing heavier pumping machinery. This, fact, with the low price of zinc, has obliged many of the mines to shut down until conditions are more favorable. The lead producers will continue to operate, as the high price of lead is very satisfactory.—Unusual activity has been noted in the Duenweg camp the past few weeks. Some rich strikes have been made. On the Walker land, northwest of the town, three companies are working, and all are in good ore. The Bayer Mining Co. has sunk 11 drill-holes on its 20-acre lease, and 10 of these penetrated a rich deposit of lead and zinc-blende at 130 to 150 ft. The ore is disseminated but also occurs in chunks, some of these weighing as much as 25 lb. On the same land the Panell Franks Mining Co. has developed shear-groud at 150 ft. in two shafts. Development has proceeded far enough to develop the ore and prepare the workings. On another portion of this tract Wilson & Winters hold a lease and have sunk a shaft into sheet-ore at 140 to 150 ft. Both galena and zinc-blende are found, the galena in the upper levels and the blende below in the sheet formation. —On the Hall land, south of Duenweg, a new silicate camp of wide extent has been opened up. About 1,156,000 lb. of this ore has been removed from the shaft erected at once. —Two others are in course of erection north of Webb City. One is upon the Bird Dog lease, and is a plant of 250 tons capacity, and the second is being built at shaft No. 2 of the Goode mine, and is of 150 tons capacity. Two shafts upon this lease have been connected by air-drifts. The Endeavor Mining Co. is erecting a 250-ton concentrating plant upon the 49-acre lease at Webb City. The mill has been removed, and a new storage-bin and crushing-room have been added. The capacity of the mill has been increased with these improvements, and the plant can operate more steadily. The skip system of hoisting is employed at this mine. —A new shaft is being sunk on the old Eclipse land, south of Carterville, and is now down 65 ft. Not a drill-hole has ever been put down on the 26 lots of the Eclipse lease, though the tract lies in the midst of thoroughly tested and developed territory. The American L. & Z. Co. adjoins the tract on the east, upon which a good deposit of sheet-ore was discovered last year. The lots are practically virgin territory, and will be thoroughly prospected.—A unique deposit of zinc-blende is found in the north Wobbl City camp. It is a soft-ground deposit on the Integrity lease, the ore being found at 100 ft. This is the only workable soft ground found in this camp during the past year. The mines surrounding this lease are all of the sheet-ground variety, and the deposit is found in hard ground at 180 to 250 ft. The 100-ton mill is kept busy and only two machine-drills are required to break the ground. This is one of the few zinc mines that are being operated with profit during the recent low price of ore. —Water in the Spring City camp, south of Joplin, has been very trouble-

sone, but in spite of this fact the Sunrise mine has been operating successfully. The 30-acre lease is now fully developed and is producing. Two shafts are being worked by the company, while the third is being sunk by a sub-lease. The ore was found at the 140-ft. level and shows a rich deposit of zinc-blende and galena. The ore is being milled by a crusher, rolls, and hand-jigs. The ground now has reached the developed stage where a mill is a necessity. A three-inch pump handles the water successfully, though the Argosy and several other properties in the vicinity have experienced considerable trouble with water. The Delta Mining Co. has again resumed operations, after being closed down in order that a concrete bottom might be put in the mill-pond to prevent leakage into the drifts. The work is now completed and operations have been started upon a large dump-pile containing a large amount of crushed rock and ore obtained during the underground development.

**NEVADA.**

**ESMERALDA COUNTY.**

Work has been begun on the Black Bird Mining Co.'s property in the Red Mountain section of the Goldfield district. The property lies between the Butte Boys and the Diamondfield Red Mountain. At a depth of 300 ft., a quartz vein was encountered a few months ago. —The Chicago Exploration Co. has recently acquired control of the Lucky Boy and the Mountain King mines, near Hawthorne, and shipments of high-grade ore from the mines have been resumed. —The first shipment of ore from the Frances Lime Point mine, in the Hornsilver district, has arrived at Goldfield, for the Nevada Goldfield Reduction Works. —The mines of the Goldfield district produced, during the week ending June 26, 300,495 tons, of an estimated value of $145,315. The Tonopah mines produced during the same period 570 tons, having an estimated value of $147,650.

**HUMBOLDT COUNTY.**

The Potter & Arnet lease, on the Massma ground, is installing a new pump and hoist, and expects to sink to considerable depth before cross-cutting. —G. H. Haynes has started the new 40-hp. hoist at his lease on the Massma Hill and will sink a 300-ft. shaft.

**NYE COUNTY.**

The Tonopah Liberty mine, 25 miles north of Tonopah, is enlarging the mill on its property to twice its present size and installing a 100-ton Huntington mill. —The Tonopah Mining Co. of Nevada has declared a quarterly dividend of 25c. per share, payable July 21. The company suspended dividends a year ago, up to which time they had been paid regularly. —Ground has been broken at the Solid Gold lease, on Round Mtn., for a new mill of 50 tons daily crushing capacity. This will be the fifth mill in the district. The Gold Bar, at Rhyolite, may build a mill some time next
fall. J. P. Loftus, president of the company, was at the property last week, and is authority for the statement that if the Homestake mill proves a success, the Gold Bar will probably build a similar plant. -The Tecopa Con., near Bullfrog, is said to be planning a 500-ton concentrating plant and the installation of a new compressor. John T. Overburg, of Bullfrog, is interested.

URBAN COUNTY.

The Western Smeltering Corporation has been incorporated to build a plant on the Carson river, 31 miles from Carson City, near the old Brunswick mine. The company has an office in Reno. The site of the proposed plant is 40 acres of land between the Carson river and the Virginia & Truckee railroad, and has a water-power of 150 hp. now available, which it is claimed can be increased to 350 if desired. The first unit to be erected will have a capacity of 250 tons, with one furnace for copper ores and one for lead, gold, and silver ores. If constructed the plant will be run as a custom smelter.

WHITE PINE COUNTY.

The Stuart Holding Co. received last week two carloads of machinery for its custom mill at Cherry Creek.—The Boston Nevada Mining Co. will increase the force of men at work on its Cumberland claim in the Osceola district. —The Boston Nevada, which owns 150 acres of placer ground at Hogum, in the Osceola district, will let a contract for a shaft to prospect some of the rich placer deposits such as have been found in the zone near the mouth of Mary Aam canyon. —The second unit of the concentrator at the Steptoe Reduction Works will be put in commission by the middle of July. —The French American Mining Co. has purchased the Macom City group of claims at Lane City, the consideration being $75,000. The new owners will start shipments at once. The same company has recently increased the working force at its properties in the Osceola district and at its Duzette group, near Lane City. —P. M. Baker has purchased 80 acres of land in the Osceola district, which includes the water rights to Baker and Lehman creeks.

NEW MEXICO.

The Anderson Apache Copper Co., five miles south of Hackita, will soon commence shipments of ore to the Copper Queen smelter, at Douglas. During the past year a two-compartment shaft has been sunk and 1600 ft. of cross-cutting and drifts have been driven. —A rich strike of gold-silver ore is reported from the hills north of Encino.—The Oil Exploration Co. has resumed drilling at its oil-well near Santa Rosa. It is now 1100 ft. deep, and the company plans to go 3000 ft. if necessary.

OREGON.

The Ohio mine, near the Columbia, at Sumpter, will soon be opened, and the mill will be equipped with new machinery. John Thomson, president of the Columbia Ex. Gold Mines Co., is interested. —The Talilima smelter, which has been idle for the last nine months, was started last week. The company will do its own smelting this season. —The Quebec mine, in the Sumpter district, in which large bodies of gold ore were opened several years ago, but which has been allowed to go down because of internal dissensions among the stockholders, is to be operated again at an early date. The mine was the scene of great activity five years ago.

UTAH.

BEAVER COUNTY.

(Special Correspondence).—There is an improvement in mining conditions reported from Beaver county, where recently a number of mines that had been idle for months past have been started up again. In the early part of the year the Cactus mine, of the Newhouse Mines & Smelters Corporation, was practically the only producing property in the several districts of the county. Since then the Horn Silver mine has contracted its output to the Ticino Smelting Co. and is ready to ship. The Hecla, Cedar, and Burning Mosquito are also shipping again. W. D. Elwell, of Boston, president of the Majestic Mines Co., who recently formed a re-organization scheme for the Majestic Copper Co., has been on the scene, has sold off the debts of the older corporation, and ordered development work started again. The Majestic mines produced a large tonnage of low-grade copper ore during the high metal market times of last year, and were among the first in the State to close after the slump came. The Indian Queen Mining Co., which recently installed heavy power equipment, is conducting a vigorous development campaign under encouraging conditions.

Beaver, June 30.

WASHINGTON.

FERRY COUNTY.

(Special Correspondence).—The lessees of the Republic mine have shipped a carload of ore for a test of value and are now engaged in heavy timbering, preparatory to new development on the upper levels. —A few men are engaged in stopping ore above the bottom level of the Lone Pine workings of the Pearl group, under the direction of the Syndicated Deep Mines management. —It is probable that the gasoline engine at the Copper Key mine, on Belcher Mtn., will be replaced by steam, owing to the abundance of timber on the property and the necessity for more power. The mine is now idle, awaiting developments. —It is learned that the report of $56,000 having been paid for the Manila mine, in Kelleysville, is true, but interest is still re- quested in the Keller smelter have paid $500 cash on a $60,000 bond for the purchase of the mine. Twenty men are employed in building a new wagon-road between the Manila mine and the smelter. A force will be employed to break ore in the mine, which will be hauled on wagons, pending the construction of a tramway. —An immense tonnage of gold and copper has been developed over a year ago in the Lone Star & Washington mine, close to the international boundary, has recently been reported as a new strike. Work on the property was suspended for the time being, during the late financial trouble in the East, but has been resumed. The British Columbia Copper Co., now owning the property, is about to start a new adit across the claims from Greatmoores creek, about 4½ miles distant from the Spokane & British Columbia railway. —A new strike of gold-copper ore has been made in an iron sulphide vein on the Lake group, about six miles south of Orient. The property will be developed with Montana capital.

Republican, June 23.

OKLAHOMA COUNTY.

The Nighthawk Mining Co., at Loomis, is putting in a 10-stamp mill at its mine, and expects to have the plant running before fall. The adit is being driven with power-drills.

CANADA.

BRITISH COLUMBIA.

The Indian Chief group of claims, on Sidney inlet, west coast of Vancouver island, recently held by ex-Governor Dewdney, have been sold to the Vancouver Island Copper Co., Ltd. Seventy-five per cent of the stock of this new company has been acquired by the Alaska & Northwest Copper Co., Ltd., of Seattle, and the other 25% is allotted to Mr. Dewdney. The cost to the Alaska Copper Co. of their share is in the neighborhood of $140,000. The new company announces that it will start work at once. The ore will probably be shipped to the Tyee smelter, at Ladysmith, although it may be sent to Tacoma. —The Tyee Copper Co. has acquired the Grafter copper mine, one of the best properties in the rich district adjacent to White Horse. The terms of the transfer are on the lease system, the Tyee company taking over the property for a period of 99 years, the latter to operate it and pay the owners a percentage on every ton of ore mined and shipped. The terms obtained by the owners are such as will bring to them a continual revenue, while the lessees, with their own smelter, can handle the ore after paying the mine owners 15% of profit to themselves. A force of men has already started work, and shipments will begin as soon as the railroad spur to the mine is completed. —A rich strike is reported in the Mistle Gibson group, Burnt Basin district. It consists of a 7-ft. shoot of gold ore that will average $90 per ton. A wagon-road is being constructed to convey the ore 4½ miles to the railway.
Special Correspondence.

LONDON.

Formation of an Institute of Metals.—Great Cobar Report.

While American mining engineers and metallurgists are forming a new society which will aim rather at professional status than at the collection and dissemination of information, English metallurgists are establishing an 'Institute of Metals,' with a purpose in the opposite direction. This new institute has been started through the energy of two Manchester men, W. H. Johnson, a large consumer of copper alloys, and C. H. Carpenter, professor of metallurgy at Manchester University. The lines of effort are analogous to those of the Iron & Steel Institute. It will discuss the metallurgy of the non-ferrous metals, especially copper and its alloys, lead, zinc, tin, and aluminum, the word metallurgy including the whole range of metal-working, and not being confined to the production of a refined bar. The membership is to be open to all those who are connected with the metal industries, and the method of election will be analogous to that of the Iron & Steel Institute, the Society of Chemical Industry, and the American Institute of Mining Engineers. To some extent the scope will overlap that of the Institution of Mining & Metallurgy, but this can hardly be helped. The Institution is primarily a professional body, and deals with metallurgy from a mining engineer's point of view. On the other hand, the new Institute will include a great number of members who would not be eligible for election to the Institution, but, for all that, are seriously interested in metallurgical operations. It is a remarkable fact that hitherto there has not been any society or publication in Great Britain making a specialty of non-ferrous metallurgy. To be quite candid, this is the reason why the Engineering and Mining Journal and the Mining Industry have obtained such a large circulation among engineers and the continent of Europe. These publications gave scientific and trade information that was not obtainable in any English publication. Other American papers, such as the Brass World, and the Electro-Chemical & Metallurgical Industry also enjoy a vogue. The Faraday Society deals to some extent with electro metallurgy, but it is too scientific and does not concern itself with practical details. At one time the Society of Chemical Industry devoted a fair share of attention to metallurgy, but of recent years the great expansion of organic chemistry has forced the chemistry of metals into a corner. The new Institute starts out with a thoroughly representative council. Sir William White, late chief constructor to the Navy, is president. Professors Goldsmid and Turner represent science. The secretaries are represented by the Hon. Odo Vivian, of Vivian & Son; J. C. Field, of Dilwyn & Co., the zinc distillers; J. D. Bonnor, of the British Aluminium Co.; Cecil H. Wilson, of the Sheffield Smelting Co.; Leonard Sumner, of the Broughton Copper Co.; Norman Cookson, of Cookson & Co., and Mr. Harvey, of Williams, Harvey & Co., the tin smelters, of Hayle; while the users of metals, the engineers, ship-builders, cable makers, and others are equally well represented. I feel sure that the Institute will be a success.

The first annual report of the Great Cobar, Ltd., in New South Wales, has just been issued. It covers the period from the formation of the company, in May, 1906, to December 31, 1907. This well known copper-producer has yielded fortunes in the past to its Australian owners. On many occasions have London promoters tried to purchase it and re-flot it over here. What prevented the success of these schemes was the enormous sum in cash required by the owners. In the successful flotation of two years ago the purchase price was £1,066,000, payable as to £800,000 in cash and the remainder in shares and debentures. The capital of the company is £1,300,000, consisting of £750,000 in shares and £550,000 in debentures. A sum of £236,000 had to be spent in extending the mining and metallurgical plant. The mine had got too deep and the orebodies too lean for the old methods to be possible any longer. With the working capital subscribed at the flotation, and also by means of loans amounting to £187,000, considerable improvements have been made, and at the present time the outfit is equal to anything in existence. Great delay in erecting the new plant was caused by the refusal of an American firm to accept the contract made by its English agent. It would be unkind to mention the name of the firm, but I will interpolate the remark that American manufacturers, to succeed in their export trade, must trust their foreign agents. In this case the firm lost the contract, and the whole work of estimating costs had to be done over again. In the end, only the new blast-furnaces and converters were bought in the United States, the steel buildings, engines, boilers, and electric plant being obtained in Great Britain. Another source of delay was the poor condition in which the mine was left by the vendors. The negotiations for the sale and the completion of details in connection with it occupied a good deal of time, and the vendors took the opportunity of extracting the best ore in the meantime, without properly attending to the condition of the mine. Up to the present time the smelting operations have been conducted at the old works, and the results are not as good as they will be before long. From the time when the company entered into possession, August 22, 1906, to December 31, 1907, the amount of ore smelted was 253,450 tons, of which 116 tons of first-class matte, and flue-dust were passed through the furnaces. The total matte produced was 15,523 tons, which was shipped to the company's works at Lithgow for treatment in the reverberatories and electrolytic refining plant. The reverberatories also treated purchased ore, slag, and flue-dust, and it is not quite clear from the report what was the actual yield from the company's own ore. The product obtained from the electrolytic plant during the period was 6114 tons fine copper, 17,166 oz. fine gold, and 104,282 oz. fine silver. The proceeds were £533,902, and other receipts brought the total earnings to £603,655. The working costs were £553,045, and London expenses £15,176, leaving a profit of £28,451. Out of this, £49,500 went as interest on debentures, £112,500 to the shareholders, the rest being retained in the company. It is interesting to note that the company has adopted a means of providing for the depreciation of the mine by arranging that £100,000 shall be set aside out of
Associate New South Wales.

Kalgoorlie, Western Australia.

Koolyanobbing Goldfield.—Horse-shoe and Great Boulder Developments.—Associated and Lake View Consols—Dust Removal in Dry-Milling.—Water-Delivery.

The gradual decline in the gold output of this State, and the failure of well-organized exploring and prospecting parties to locate new fields, so that new mines could keep up the returns of those which are being reduced, has of late made the future of the mining industry look rather blue. It is with peculiar pleasure, therefore, that we are now able to report the opening up of a new field in the Koolyanobbing Ranges, 25 miles northeast from Southern Cross, in the Yilgarn goldfield. This goldfield has an area of 15,593 square miles, and since 1892, gold to the value of $8,419,000 has been obtained; the annual yield, however, has never been over $500,000. Most of this is produced from mines near Southern Cross.

It appears that prospecting has been going on in the Koolyanobbing Ranges for some time past, but only toward the end of April were any leases applied for. The new field appears to be approximately 10 by 6 miles in area, and consists of schists, ironstones, and conglomerate, full of quartz veins and outcrops. It is not one for a great rush of 'dry-blowers' and the like, but from all accounts will be a field for a lot of careful work in development, and probably one for small companies with moderate sized batteries. However, in the course of a few months we shall be more able to judge the place. Everyone who has visited it is rather optimistic, but moderately so.

The cross-cut at 2000 ft. in the Horsehoe went through a ledge 5 ft. wide, worth $13 per ton. Driving at 2200 ft. in the Great Boulder still reveals fine ore. The Associated announces ore reserves are 439,414 tons at $10.30 per ton; and the Lake View Consols 172,529 tons, worth $6.70 per ton. The former mine is about to install an Edwards duplex roaster, and the tonnage will be brought up to 12,000 tons monthly. This company already has 15 Mertons and one Associated furnace at work. The Great Boulder is also building an Edwards duplex, making two of this type, together with 12 Edwards tilting-type and eight Mertons with extended finishing hearth, now running. Forty thousand tons of ore is treated monthly, but a mine like the Boulder is capable of more than that. On an average 12,000 tons of old slime are re-treated per month, either by the Ridgway machines or the filter-press plant. Many interesting comparisons should be obtained in this mill, as there are Krupp ball mills working along with Griffin mills; Edwards tilting, Edwards duplex, and Merton roasters, and the Ridgway suction machines, with filter-presses of the hand-screwed and hydraulic types. Attached to the Krupp and Griffin mills in the several dry-crushing plants on this field, are fairly powerful fans for drawing off the dust that would otherwise float about, making work very unhealthy, and occasioning losses. The fans blow the dust into long narrow houses with Hiessen walls and ends. When a sufficient quantity accumulates it is treated along with the ordinary ore in most cases. The Kalgurlis treats its dust by agitating with bromo-cyanide. The Associated Co. is now experimenting by blowing the dust onto the second hearth of each Merton furnace, where part will be roasted and part go into the main flue, thus saving trouble with the unhealthy dust houses. Dust caught in the flues from the furnaces must be passed through again. On first thought one would think that the cold draught from the fan would cool the roaster, or that the dust would put the roast off. This proves not to be so, and the process appears to be a success. There has been some talk of erecting Cassel plants to treat the huge dumps of residue on the Oroya-Brownhill and Ivanhoe mines. These consist of sand, pan and tube-mill slimes, and roasted concentrate residue. The Cassel plant on the Lake View Consols was designed to treat 100 tons daily, but so well has it worked that in 24 days 4970 tons were treated, yielding gold valued at $52,090. If this is a sample of the residue dump, it will be pleasant to treat several hundred thousand tons of similar stuff.

The output for April is shown in the following table:

Loss.

Total dividends to April 30, 1908, paid by all mines in Western Australia amount to $83,725,000.

Rain was badly needed at some of the outlying centres in January, but since then we have had about five inches, and all dams are overflowing. Some 229 acres of crops are in at Coolgardie, and the owners will do well, as the soil...
is rich. The amount of water used by the Kalgooilie group of mines in March totaled 25,300,000 gal., supplied by the Government water-scheme. Our weather is very wintery, the mercury dropping to 33° recently, making a severe change from the hot weather of January, when the temperature reached 114 degrees.

MEXICO.

It would seem from recent events that a spirit of unrest pervades the Mexican Republic. Whether it will lead to trouble or not is difficult to say. During the past week the railroad employees have again been discussing the advisability of requesting or demanding that all foreigners be dropped out of the railroad service and their places filled by Mexicans. It is said that Messrs. Felton and Brown, presidents of the Mexican Central and of the Mexican National railroads, respectively, have replied that the employees will be chosen in accordance with their fitness, without regard to nationality. There was also a slight disturbance at Casas Grandes, in the western part of Chihuahua, a few days ago, where report has it that a small band, headed by Santa Ana Pires, a former revolutionary, was attempting to stir up insurrection, but some twenty or more arrests have been made, and nothing more has been heard from that district. Finally, word has come from Saltillo, capital of the State of Coahuila, that some 500 to 500 men had risen, and overcome the police force of the city, had helped themselves to guns and ammunition, and started for Torreón with intent to kill Governor Cárdenas, gather recruits, and start a revolution. Two immediate results of this disturbance have been, first, a change in the routing of the Mexican Central pay-car, so that it will go from Saltillo to Montereý and thence across to Torreón, instead of directly from Saltillo to Torreón over the Coahuila & Pacific railroad, as at first intended; and, second, the serving of notice from the Well-Fargo Express Co. that no money would be accepted for consignment to or through Torreón. Absolute verification of the above and correct information as to the seriousness of the disturbance cannot be obtained at this writing, but from the most conservative information available now, it would appear that the disturbance was much in the nature of a bread-riot. A large number of the unemployed, who are beginning to get hungry, had evidently banded themselves together to hold up the Mexican Central pay-car on its return from Saltillo, but the pay-master got word of it and ran around them. In this connection, it can frequently be heard in Chihuahua that unless the Greene Gold-Silver Mining Co. distributes a good sum of money among its laborers in the near future, there will be trouble in the Ocampo district, in the western part of this State.

In news from Saltillo and Torreón the alarmists claim to see the hand of one of Mexico's former ministers of war, who, rumor has it, is only biding his chance. This suspicion would, of course, come to the mind of anyone acquainted with recent Mexican history.

Within the last week the Mexican press has been giving considerable space to the opening by Messrs. McQuatters and Sheppard, contractors in Chihuahua, of what they call the Bismuth King, located near Culiacan, in the State of Sinaloa, where ore running from 13 to 26% bismuth is reported to have been opened up. The property is heralded as the only producing bismuth mine on the North American continent. A chemical company at St. Louis is reported to have contracted for the entire output of the mine. The above is rather amusing and attracted my attention for two reasons: First, in a recent statement, Mr. H. E. Waring Passo appeared the statement that "a deposit of bismuth ore of sufficient size to make its mining on a large scale worth while, would yield sufficient of the metal to reduce the market price to much less than it has been in recent years; but it is possible that if the market were not artificially contracted, and the metal were mined and smelted without restriction, new uses would be found for it, and manufacturing on a larger scale might become a commercial success." Second: the Ballard mine at Leadville, Colo., has been a good producer of bismuth for the last ten years or more. It is to be hoped that the Bismuth King, in Sinaloa, is as good as reported, and that Bismuth Queen, which is being opened up by the same people, may prove a worthy partner. The Choix Consolidated Mining Co., a Los Angeles concern, is operating at Choix, Sinaloa, under the
direction of A. M. McDermott. The Sierra Madre Mining & Development Co., controlled by St. Louis capital, is also operating in four different districts near Cholix, under the direction of A. W. Warwick, formerly of Colorado. The Pacific Exploration Co., also operating near Cholix, is doing a great deal of development and experimental work, and the El Carmen Gold Mining Co., at San Lorenzo, is opening a large body of high-grade gold and silver ore in the San Manuel mine. The El Carmen mine, belonging to the same company, is being uncovered and re-timbered, preparatory to sinking the shaft another 200 ft., while grading is going forward for the erection of a cyanide mill. Only the lack of railroad facilities prevents the company from being a steady shipper. The Kamloops, Mexio & Oriental Railroad will be operating to Cholix by January 1. The Lolo Mining Co. is now operating the Lolo mine at Buenos Aires, near Cashuhrachic, Chili. The mill has a daily capacity of 15 tons, and will be started up as soon as the rains begin. Upon the completion of the Mineral Belt railroad at Gwennajuto the various mines of the Securities Corporation Co., Ltd., in the L.A. Lux district, are to be equipped with new machinery, which will include a 1000-ton stamp mill.

**BUTTE, MONTANA.**

It is likely that the Great Falls smelter of the Boston & Montana Co. will remain out of commission another month, as the big flood did great damage to the plant. The Great Falls Smelter is having its usual troubles, the consequence of the flood, the ice jams, and other local conditions. The smelter is expected to resume operations again.

---

Northern railroad between Butte and Great Falls is open again, after having been tied up through washouts for more than three weeks. With the exception of the Boston & Montana Co., all the subsidiary companies of the Amalgamated are again running full capacity, and so are the North Butte, Butte Coalition, and Original companies. The June copper production will likely fall below 20,000,000 lb. because of the interruptions by the floods.

The Parrot Mining Co. has not yet reached normal production, but is conducting development work on the lower levels with the object of opening the veins down to the 2000-ft. level. In the Parrot property the mining is confined to the 1590, 1500, 1600, 1700, and 1800-ft. levels, the ore below low-grade. There is a body of high-class ore on the 1200-ft. level, which was left undisturbed a long time on account of the extreme heat. About 7000 men are now employed in the Amalgamated mines, since mining has been resumed in the Neversewet, West Gray Rock, and Mountain Con. mines. The Mountain Con. is working through a shaft 2200 ft. deep, and will yield about 660 tons of ore per day when operated at full capacity. At the Gray Rock the old steam plant has been replaced by electric equipment. The Amalgamated output is about 8500 tons of ore per day, to which the Anaconda, Boston & Montana, Butte & Boston, Trenton, Parrot, and Washoe contribute.

Ex-Senator W. A. Clark says: "I do not look for any marked improvement in the copper trade until industrial conditions get back to normal. Our export trade keeps up well, but the consumption of copper in the United States is far from what it should be. We cannot expect conditions to improve much in the metal trade until the factories at home are turning out engines, cars, and machinery that require copper in construction, such as electrical machinery, and everything connected with electrical installation. In other words, the industrial conditions all over the country must improve before we can look for improvement in copper. Most of the trouble with copper now seems to be at home, and until our local industrial conditions grow better there cannot be much improvement in the copper trade." Mr. Clark said he had no information of any movement among copper producers to form a combination for the regulation and control of output and prices.

The Cooke & Montana Mining Co. is making preparations to begin operations in the New World district, near Cooke City, where activity has been stimulated by a proposition to build an electric railway from Columbus to Cooke. The property has been opened by an adit and drifts at a vertical depth of 300 feet.

Butte officers and stockholders of the North Butte Extension Copper Mining Co. are still without information as to the reasons for the sensational drop in the price of the stock on the New York curb, and the failure of the company to pay its most pressing debts. The property of the company in Butte is in good shape, and intrinsically the stock is worth many times more than it was when selling at $3 and $4 per share. The total indebtedness now due is not more than $12,000, though the company owes something on the purchase price of some interests in different claims. There are five known veins in the company's ground, including the big Blackrock vein. President Van Brunt and his associates have already put $250,000 into the company, in the purchase of property, installing a plant, and doing development work. The Butte-Baikaiava Mining Co. is continuing development and has its shaft down 700 ft. Cross-cutting is being done on the 700 and 900-ft. levels. In the course of development some ore has been taken out, and several carloads are in the hins. It is also announced that the company has decided to erect a steel head-frame, to take the place of the...
MINING AND SCIENTIFIC PRESS
July 4, 1908.

wooden one, the new one to be provided with self-dumping skips similar to those in use at the large mines of the district. The new process has been provided with electric automatic sawing machinery.

The new-process zinc plant at the Lexington mine of the La France Copper Co., has been shut down temporarily. For some time it was run only half-time, though the company has refused to purchase custom-ore, many lessens about Butte being anxious to sell ore to the plant. The injunction and navigation suit brought against the company by people who reside near the mill is presumed to have had some influence on the suspension of operations. The company has been unable to pay its running expenses for some time, which makes it appear that the new zinc-separating process has not yet proved a success.

The Butte-Montana Mining Co. is urging stockholders to join the company, and the local smelter-broker is trying to organize. The stock is selling on the local market at 38c., and stockholders are promised 75c. per share, at which price the brokers promise to sell the stock of the shareholders pro rata after the brokers have sold the treasury stock, which they have agreed to take if the pool can be formed. The company owns the Alex. Scott mine, adjoining the Colusa of the Boston & Montana Co. The latter company has been sinking the Alex. Scott shaft to connect with the Colusa for ventilation, and it is down 1200 feet.

The Barnes-King production was greatly curtailed in May, and is curtailed even more during June on account of heavy rains. The latest monthly report for April shows 6445 tons of ore mined, of which 10% came from the south end open-cuts and vicinity, above the 200-ft. level; 62% from the north end open-cut, and 28% from the Santiago adit. In the mill 6445 tons of ore were crushed and leached, the heads averaging $4.19 per ton and the tails 87c. The leaching has been a little unsatisfactory, the fine material from the north end giving quite irregular results. The bullion output for April was 2,130.42 oz., netting at the United States assay office $25,758, less $131 for assaying. No statement respecting adit stock is made, but it is understood that the earnings were a few hundred dollars in excess of the cost of operation.

The Anaconda Co. has for some days been engaged in reopening the Modoc mine. A new head-frame and 100-hp. electric hoist have been installed. The mine will be opened principally for ventilation and safety, as it is connected with the Modoc mines of the Anaconda Co. The Modoc shaft has three compartments, the lowest of which comes from the East that the Pittsburg & Montana Mining Co. is being reorganized. The mines and the smelter are running at their full capacity of about 150 tons of ore per day. It is also reported that the Curtis-Majors Mining Co. has been financed, and that development work on its properties in the southern part of the city may be started soon.

SALT LAKE, UTAH.
U. S. Smelting, Refining and Mining Co. Accepting Ore. — Tintic Smelting Co. — Taylor & Brunton Sampling Co.—Low Costs by Utah Copper Co.—New Concentrator at Park City.

The fact that the United States Smelting, Refining & Mining Co. is accepting ore again is taken as evidence that the Bingham Junction lead smelter is nearly ready to resume operations, but this time guided by the regulations provided in the modified decree issued from the Federal Court. The closure of the plant about six months ago was a result of the adverse decision in the noted smelter-smoke cases.

Last week the ore-purchasing department received consignments of ore from the Mammoth and the Grand Central mines in the Tintic district, with several additional lots from the southern Nevada camps. The management, nevertheless, is unwilling to name the date on which the fires will be actually kindled, saying only "it will be some time in July." There is no doubt that the long spell of rainy weather has greatly interfered with construction, but the skies have cleared and work is being pushed vigorously. For like reasons, the building of the new lead-copper smelter in the Tintic district has been materially handicapped; but the management gives assurance that certain troubles in the original design have been overcome, and that the initial unit of the lead smelter will be placed in operation within three weeks. The copper furnaces, however, will not be ready before September. The Tintic Smelting Co. last week placed orders for additional equipment sufficient to double the capacity being directed to the copper department. When completed, the plant will handle form 600 to 800 tons of lead ore and from 500 to 600 tons of copper ore per day. It is strongly hinted, since this move was made, that the Tintic company is to become an ally of the United States Smelting, Refining & Mining Co., but the report still lacks confirmation. Co-incident with the letting of the contract referred to, the Auger & Brunton Sampling Co. announced its intention of building a sampler in the Tintic district to begin with a capacity of 600 tons of ore per day. It now seems likely that the railroads will grant the request made of them for common-point freight rates for Tintic. Lack of this advantage has herebefore stood in the way of making the Tintic district an important smelting as well as mining centre. In many respects the location is ideal for a large smelting enterprise, being remote from the farming districts and accessible by both the Harriman and the Gould railroad systems. The Ogden smelter, operated by the Independent Smelting Co., will resume treatment of custom copper ores this week. The plant is equipped with one copper matting furnace. The ore congestion at the Garfield smelter of the American Smelting & Refining Co., is still unrelied, but more furnaces are being added to the equipment, and it is anticipated that the demands will be fully met by next autumn.

The successful achievement of the Utah Copper Co. in May has attracted widespread attention in copper circles. During that month 4,139,529 lb. of copper was produced, at a cost of 7.7c. per lb., as against 3,325,000 lb. in April, at a cost of about 7.0c. per lb. It is reported that expenses are slightly better, as the tenth section of the Garfield concentrator is now in commission. A quarterly statement, giving details regarding the company's operations in Bingham, will be issued to the shareholders shortly after July 1.

The American Flag Mining Co., at Park City, will begin the construction of a concentrating mill at its mine in the near future. Until the recent restoration of the Ontario No. 1 adit, the mine was unable to operate the deeper portion of its mine. Last week workmen reached the face of the adit in the Daly West Co.'s ground, and the plan outlined several years ago to develop the mine at that depth will now be carried out.

Samuel Newhouse of Salt Lake recently acquired an interest in the Prince Consolidated mine and other properties in Pioche, and has announced his intention to build a smelter in the camp in the near future, the initial unit to have facilities for treatment of 500 tons of lead-silver ores per day. Mr. Newhouse asserts that the plant will also do custom work.

The Uncle Sam Consolidated Mining Co., operating in Tintic, paid dividends last year to the amount of $79,000. Ore shipments amounted to 1,220,855 tons, netting $52,545 per ton, or $102,752. Production ceased November 15 last, owing to the smelter-smoke casts, which resulted in closing down the Bingham Junction smelter.

At meetings of shareholders of the Swansea and South Swansea mining companies the consolidation and organization of the Swansea Consolidated Mining Co. was ratified. The property involved is located in Tintic.

It is probable that work will begin on the reconstruction of the Sunshine mill, near Mercur, about July 1. The Sunshine mine contains a large tonnage of low-grade gold ore, which the former owners were unable to treat successfully. Some time ago the mine came into the possession of parties identified with the operation of the Consolidated Mercure Mines Co., who concluded that the difficulties were surmountable by the Consolidated Mercure mill methods.
Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, smelting.

Scale prevention by the use of boiler compounds is more effective if the chemical, whatever it be, is added continuously in small quantities.

A hard surface and a soft centre for a large mandrel, punch, or die may be secured by giving the tool a quick surface heat, the core remaining comparatively cool, and then plunging it into a cooling bath.

Phonolite has so pronounced a tendency to split into thin sheets that it is often called porphyrschiefer and hornschiefer by the Germans. The Bohemian occurrences of phonolite possess this characteristic of fissility in a more marked degree than deposits elsewhere.

Keys for fastening pulleys to shafts should have a width equal to one-fourth of the shaft-diameter, and a thickness equal to one-sixth. They should be tapered 1/16 in. per foot. The depth of the key-way in the shaft should be equal to two-fifths of the key at its thickest end.

Selenium, because of the peculiar fact that its conductivity is very much decreased in the absence of light, has led to a number of novel uses, among them being the automatic lighting and extinguishing of gas burners, and for measuring the quantity of Roentgen rays in therapeutic applications.

Self-glazing fireproof clay for making crucibles, retorts, or for lining furnaces may be made, according to a recent English patent specification, of a mixture of dried and powdered common clay, finely-ground sand, and rock salt, in about the proportions of 66 lb. of clay, 46 lb. of sand, and 9 oz. of powdered rock-salt, mixed with water.

United States standard thread differs only from the V-thread in that the sharp top of the latter is cut off and the root between two adjacent threads is filled in. The amount taken from the top and added to the root is one-eighth of the height of the V-thread, thus making the height of the U. S. thread three-fourths of the depth of the V-thread.

The Wye level consists of a telescope mounted in a pair of vertical Y-shaped supports (from which it may be removed), with a spirit level attached. The Dumpy level differs from the Wye level only in having the telescope immovably fixed to the supports. As usually made the latter gives an inverted image of the object. Of the two, the Wye level is easier to adjust, and more often needs adjustment.

Magnetism salts are the most highly corrosive of the substances usually found in the waters of springs or streams destined for boiler use. In addition to their indirect corrosive action, if magnesium sulphate in any considerable amount be present with lime carbonate, 'hard-scale' will be deposited, the hard-scale consisting of lime sulphate which is precipitated, while magnesium bi-carbonate is formed in solution.

Angular convergency, $a$, of two meridians is $m \sin L$, where $m$ is the angular difference of the longitude of the meridians and $L$ is the mean latitude of the two positions. The linear convergency, $c$, for a length, $l$, is $l \sin e$. For latitude 40°, the difference in length between the north and the south sides of a township (six miles square) is 39.6 feet. One degree of longitude at a latitude of 40° is equal to 53.05 statute miles.

Slip in a leather belt is usually caused by the belt being too loose or too narrow. Heavy belts should be drawn together in place on the pulleys, when they are to be laced, since the edge of a wide tight belt is invariably stretched when run onto the pulleys, giving a tendency to the belt to run to one side, as well as to slip. When a belt becomes dry and loses its pliability, put on a mixture of tallow, castor oil, and a little bees wax, but never any mineral oil.

Heating small tools for tempering in a bath of sand is an excellent method. A suitable tray covered with about one inch of pure white sand, supported over a series of gas burners, is employed. By first burning all the impurities out of the sand, false colors will not be shown on the articles being tempered. The article, if small or thin, can be laid on the top of the sand, but if large it should be buried in it, only a small part of the surface being exposed to show the starting of the color.

Case-hardening of iron and mild steel is a process whereby the surface of the work is converted into steel and hardened. This is accomplished by heating the work in contact with a material rich in carbon, which gives up its carbon to the work. Small pieces may be case-hardened by the following method. In a suitable crucible, melt equal parts of cyanide of potassium and common salt, taking care not to inhale the fumes, which are poisonous. When the fluid has attained a bright-red heat, immerse the articles in it for five or ten minutes and then transfer them to a deep tank of water.

Llamas are able to carry a load of 52 kg. (equivalent to 114.4 lb.) from 12 to 15 miles per day of 12 hr. over mountainous trails reaching altitudes often as great as 16,000 ft. One freighter takes charge of 50 animals. The average life of a llama is from 6 to 8 years, beginning to serve at 2 years of age, but they can only be employed about 15 days in each month. They will thrive upon inferior pasture where most animals would starve. Llamas sell at prices equivalent to $3 to $5 gold. The hair is made into ropes 25 to 30 ft. long, which is used to fasten on the loads in packing. It is also woven into mantles, and the hide with the hair on makes a soft beautiful rug. The dung, like that of the camel in the Orient, is dried and used as fuel. In Peru it is called 'tacua,' and is employed even in reverberatory furnaces. It sells at $5 to $7 gold per ton.
Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

A Sidelight on History.

The Editor:

Sir—The elevation of Theodore Roosevelt to the Presidency of the United States was a result of the discovery of the silver mines of Potosí in the year 1545. When Pizarro had conquered the Incas, and was building Lima, he sent one of his brothers to take possession of these already famous mines, which were soon made to yield enormous riches. One-fifth of the silver produced was paid as royalty to the Spanish Crown. What the kings of Spain drew, first and last, from Potosí, can only be guessed at; but official figures show that for one relatively short period, from 1566 to 1615, their royalty amounted to 259 millions sterling. It is certain that Potosí gave more wealth to the kings and people of Spain than did all other American sources put together, and for many years after its discovery Spain was able to hold the supremacy of the world.

History and observation show us that the Spanish people during this period could not have been the greatest people in the world—they were only the richest. Their kings, also, absolute in those days for good or ill, were one and all steeped in bigotry and superstition. Under rulers of this type, or with a people lacking the inherent qualities required for world-progress, Spain should have quickly fallen back. She did not, till later—because her kings were immensely rich, with the riches of Potosí, and could make their money effect what their characters lacked. Spain’s wealth was mistaken for real power. Poorer countries became her satellites, and her money no doubt cemented the alliance with Rome and with Rome’s powerful lever, the Inquisition. As wealth poured into Spain, her prestige, in a poverty-stricken Europe, rose ever higher. She was feared at home. Abroad there was none to oppose her. What simpler, then, than her wholesale policy of annexation? Peru, the whole of South America except Brazil, Mexico, and the countries to the north, Central America, and the islands of the Caribbean were taken one after another. But Spain’s seemingly wonderful hold on the New World was more or less an accident. Her colonizing was only made possible after unheard-of cruelties and wholesale murder of the Indians, and had it not been for the wealth of the mines, the expeditions would have returned in disillusionment to Europe. But with such great riches pouring back, everything became possible, Spain kept her position in Europe. She made the Church her first ally. She kept the poorer nations in fear. She controlled the sea, and no one dared interfere with her great schemes in the West. In due time she owned nearly all America. It looked wonderful; but it was unreal. Stripped of their wealth and prestige neither the kings nor the people of Spain were fit to inherit the Empire which accident had made theirs. It was the wealth of Potosí, not the qualities of her people, which gave Spain her American colonies and enabled her to retain them. But for this wealth, securing her prestige and powerful allies, Spain would have had at that time to share the New World with Portugal, Holland, France, Austria, and perhaps even England—all fitter nations to retain and develop colonial possessions. Without her wealth, which blinded Europe to her true status, her inefficiency as a colonizing power would soon have shown itself, and as effectiveness overtook her, her American possessions would, one after another, have passed in those early days into more capable hands.

My argument then is this: The tremendous grip Spain got on America was due, more than anything else, to the mines of Potosí. If there had been no Potosí, there would have been no Spanish empire in America. True, Spain might in the beginning have owned possessions here and there; but because of her incapacity to govern and develop them, these would have been gradually wrested from her. Thus, at this much later date, there would have been no war between Spain and the United States in the year 1898. The rest is soon told. It was that war which gave Roosevelt the opportunity, which otherwise might never have come to him. Heroism in the field, backed by a strong personality, secured him the popularity which carried him to the Governorship of New York State; while his peculiar efficiency there carried him to the Vice-Presidency. McKinley’s death, it seems to me, only hastened his elevation to the highest post.

The Presidency of Roosevelt is a strange link in this chain of cause and effect. From 1545 to 1908 is a long time; but who shall say that the discovery at that mountain in far-off Bolivia has ceased to be an influencing factor in great affairs, or that the dynamic forces then set in motion are not destined to influence history as much in the future as in the past. It seems to me that the discovery of Potosí has vitally affected the history of all America, of Spain, and of the Catholic Church. Closer enquiry would, no doubt, show us that it had greatly affected the history of the whole world. Today the people of Potosí, still 150 miles from any railway, conduct a respectable tin-mining industry, and produce only a little silver; for tin is high and silver is low. There is a great deal of tin and silver ore still to work, but it is unlikely that the mountain will ever again flood the world with wealth. Taken all in all, Potosí has been one of the wonders of the world, and has exercised enormous influence on the fates of nations.

J. H. Curb.

Valparaiso, May 11, 1908.

Mineral Law.

The Editor:

Sir—it is evident from the letter of Charles H. Shamel in your issue of May 23 that he is an ardent champion of the ‘law of the apex’. Until I saw this letter I did not know that Mr. Shamel had previously referred to my criticism of the apex law in Economic Geology. Having now read with care his contribution to the discussion in the journal mentioned, and his recent letter in the MINING AND SCIENTIFIC PRESS,
July 4, 1908.

MINING AND SCIENTIFIC PRESS

17

I must still beg to maintain my position with reference to the question in hand.

The discussion on this subject has been long, and the two parties, defenders and opponents of the law of the apex, appear to me to have presented a sufficient amount of evidence to have exhausted their ammunition, as it were. If it were conceivable that the case could be presented before such an international tribunal as I have previously suggested, the pleading on both sides being weighed, I believe that the opponents of the law of the apex have nothing to fear. Before the court aforesaid I should be bold enough to hope that my small portion of the sum of evidence already presented, together with Mr. Shamel's specific attacks on my several exhibits, would obtain a hearing.

It is gratifying to know that in the case of our valuable possession, the Philippines, the mining code recently drafted follows the general precedent of rights restricted to vertical boundaries on four sides. In the United States it seems improbable that any fundamental change in the provisions of the apex law is to be expected. It is also to be feared that a continuation of the discussion concerning this vexed question will result in nothing more profitable than the intellectual pleasure which it affords to the participants.

London, June 7.

C. W. Purlington.

The Editor:

Sir—I have noted some recent discussion in your paper with respect to the apex law, and if you will permit me, I must offer some exceptions to the attitude assumed by your correspondents. I have had many years' experience with and many years' litigation over extra-lateral rights, and at times have been almost converted to the advantages of the Mexican and Canadian law; further thought, however, has shown me that they are hardly any better than the American. Now the only remedy that I have seen proposed to mitigate the evils of extra-lateral rights is the revoking of that law and the limiting of rights within vertical lines; but I am forced to contend that one alternative is as bad as the other; both are right and both are wrong; therefore we must look to a compromise between the two. A little actual experience in the courts with the ownership of valuable mining ground at stake, will at once show us the fallacy of the assumption that the decisions of State and Federal Courts have cleared up the inaccuracy, looseness, and vagueness of the mining statutes. A few good points perhaps have been made, but in many cases there is no definite rule at all, and as a result justice becomes debased into personal opinions, and often the prejudices of a judge or jury left to interpret the miserably elastic statutes whatever way he wishes. The decisions are far from satisfactory.

But your correspondents have not gone far enough in their reasonings, and a deeper insight into the rights and wrongs of the apex law will bring us to a new conclusion. We are told that the vertical lines doctrine is unfair and cheeoks the development of good mining territory. Why? Because if a man owns a claim 600 by 1500 ft. and has a ledge cropping strongly on the surface, he is not going to expend a large sum of money to open it up, when it is likely to dip right out of his ground and into his neighbor's at any moment, and leave him with little or no compensation for his work. Therefore it is argued the law of extra-lateral rights should be left in force, and there the reasoning stops. It is for this purpose that I have written you, to ask your readers to go further. What about the man who locates a claim side-lining the one we have just discussed? Smith locates the Bossie B. claim, and you give him extra-lateral rights to follow his vein anywhere, so he will be justified in developing his ground. Now Brown comes along and locates the Katy K. claim alongside of the Bossie B., both locates showing strong cropplings, with distinct strikes, but of course no positive proof of dip because of a possible 'buckle' in the vein, or other irregularity. Brown has as much money as Smith, he is as well able to make a producing mine as is Smith, and he should have exactly the same inducements and certainty of reward. Is that the case under the present apex law? We must answer, "No." If Smith's vein dips into Brown's claim and both veins should unite, Smith gets everything from his apex to unlimited depths, and although Brown has spent as much money as Smith, he only gets to the point of junction. The law works both ways; and after years of experience with laws of the United States, Mexico, and Canada, as a mining detective and operator, I have come to the conclusion that we should find a new solution for the troubles resultant from the vagaries of veins. Either the apex law should persist, with the qualification that if two veins unite on the dip, the work must be carried on jointly below the point of junction, with equal division of profits, or else mining claims should give a sufficient width of ground on each side of a vein to cover a large area on the lode on its dip. A claim should be 1000 ft. long by 2000 ft. wide. Most locators stake out two or three claims in any case, so why not take advantage of that fact and authorize a claim equal to two or three present claims in width. This would do away with most of the trouble. It is not necessary to upset the entire statute, but make a few necessary changes.

Seattle, Washington, June 11.

C. J. Kennedy.

The Editor:

Sir—In an editorial on the Yaqui trouble in Sonora, in the issue of June 6, 1908, of your valued paper, I note that you make several rather unfavorable indirect remarks concerning the Mexican officials, and if I am not mistaken, in another recent issue, you compared them to your old 'Frisco' officials. I would like further information citing exact cases where the officials have been guilty of grafting, etc. I am also aware of the fact that "certain men" seem to be inclined to make a great many "remarks" concerning the Mexican soldiers, officials, and system of government in general.

Graft in Sonora.
The story that army officials are grafting reminds me of a story told of a United States officer who was exploring in the Southwest about a quarter of a century ago. It seems that a pack-mule went over the precipice and the pack was never seen again. When he came to make up his ‘returns’ he ‘loaded’ all his ‘unaccounted for’ on that unfortunate mule. I do not remember how much it was, but think that it was about a carload of ‘stuff’. Upon receipt of the report, the quartermaster general promptly telegraphed him to buy 1000 mules like the one that went over the precipice. From this time on the United States officers have had another way to ‘account for’ the ‘unaccounted for’ supplies, etc., besides the time honored quarterly garrison fire. From what I have seen, it seems that the two stories are about of equal weight.

Regarding the Mexican soldiers, I have found them to be brave, good shots, keep their rifles in good shape, and keep a good supply of ammunition on their persons. To be sure, they are not dandies when campaigning in an arid country where it is often impossible to get enough water to wash their faces. I do not recall the soldiers losing a single American or foreigner that they were escorting, whereas I know of quite a number of different Americans that did not and would not take escort and were killed by the Yaquis. I am under the impression that the Mexican soldiers are far more active in the pursuit of the Yaquis than you are giving them credit for. It must also be remembered that the Yaquis are intelligent, strong, have great power of endurance, and are remarkable travelers. Col. Powell in his ‘Customs of the Service’ says of the Mexican soldiers, they live on tortillas and frijoles, and stand the hard campaign without much sickness, especially from dietary causes. Ask any old officer what that means. Several years ago I was going to Sinaloa, by way of Guaymas; at Hermosillo the train was delayed, and I, in company with the others, commenced to look around; about the first thing that attracted our attention was several box-cars filled with Yaqui prisoners of war guarded by Mexican soldiers. It soon became evident that we would be tied up for some time, and being about midday in the late summer, it was decidedly warm. The captain of the soldiers took the Yaquis under guard and put them in the shade of the depot, and kept them there until the train was ready to leave. The Americans were quite surprised that a Mexican soldier should be so considerate of others.

Regarding the Mexican system of government and officials. They seem strange at first, but I have found the officials usually honest and square in the discharge of their duties, and I think that many parts of the Mexican system of government could be copied with great profit to ourselves. I seriously doubt if there is any foreign country where we can get as near the square deal as we do in Mexico. As to tying up the country, I do not believe it possible to keep the American prospector out of hell if someone would show him a little gold and tell him that he got it there. When the prospector finds ‘colors’ and the miner gets a sufficient showing, we will put in a railroad or suitable transportation system. It does not matter if they cannot get a pack-mule into the district before we get our lines in operation.

Speaking of railroads reminds me that under your Guaymas correspondence some time ago, you made some remarks regarding poor construction of the F. C. de C. R. Y P., which is now building down the west coastal plain of Mexico. Among other things you said: ‘Construction is crude, all cuts of more than a metre being “shoo-died” and gulches crossed on cribbed ties.’ It takes an average cut or fill of 7 by 10 ft., with the accompanying opening, to equal the cost of the track complete, depending somewhat on the locality and other things. Roughly, this is about one-half the cost of a railroad. This shows the absurdity of the first part of your report, and as to the second part, we always, especially in an arid country, try to keep the rails up to the end of the finished grade, so that we can get supplies and water easily. It is comparatively easy and costs almost nothing to build a little cribbing of ties, and take the steel across the arroyo. Then at our leisure we can dump the bridge material and other supplies from the cars and build the bridge. This saves expensive handling, tram haulage, and breakage, and keeps the work better under control of headquarters.

CHARLES KIRBY FOX.

Pomona, California, June 8, 1908.

[We congratulate our correspondent on his intent to defend the Mexican Government against unjust criticism, since such a spirit is not often enough in evidence among our countrymen. Our comments on Mexican banking in the issue referred to show clearly the high regard in which we hold our neighbor Republic. We are not criticizing that Government, nor did we intimate the inability of the Mexican soldier to suppress the Yaquis if given the opportunity, under a well-planned campaign, to do effective work. We merely directed attention to the notorious grafters who have brought reproach upon northwestern Mexico for many years. We are ashamed that even the lime-light which has been turned upon the corruption in San Francisco has not illuminated the dark places and rendered dishonesty impossible, and we are aware that a host of right-minded gentlemen in Sonora deplore the evils which have continued in their midst through the degrading influence of graft-money. Unfortunately, in Mexico as in the United States, the better citizens are less likely to be in power than those who have more selfish aims than that of good government.—EDITOR.]

Producer-Gas.

The Editor:

Sir—Ancient tradition and mythology record that the giant, Typhon, cut out and carried away Jupiter’s sinews, which Mercury afterward stole and restored again to Jupiter, thus giving to the king of the gods the means for his victory over his rivals. It is not a far-fetched figure to say that our modern Jovian manufacturer is fast losing his sinews, and in his struggle for cheap power is running a fair chance of defeat, unless some Mercurial spirit of invention shall come to his assistance with the wit,
born of necessity, and the determination sprung from faith, to command success. For the seeker after cheap and reliable power, these sinews of strength are to be found in the gas-producer and the gas-engine.

Producer-gas is a very real thing, though it has baffled the best wit of many an attempted definition. Perhaps we may say that producer-gas is the partly burned complex mixture of gases made by the complete breaking down of the structure of fuel under the combined action of air and steam at an elevated temperature. Thus anthracite-coal gas from the producer leaves a fuel reduced to ashes; but the gas itself is consumed only to the extent of losing about 15% of the power originally available in the coal. With softer fuels, there is liable to be more volume of combustible matter in the resulting gas, though it does not always follow that less than 15% of the power originally resident in the fuel is charged off for changing the fuel into volatile form; but, at all events, the resultant gas is rich, and the commercial possibilities are worth much effort. It will take any good student—the practical man, I mean—a year to master the principles of the gas-producer and the gas-engine, so that he can eat, drink, and sleep on them by instinct. I do not mean that a man can not learn to run a good gas-producer or a good gas-engine, or both, in a few days. Any good man can run these mechanically, after a few hours of study and observation; but to know all the turus and twists of the nature of this kind of furnace and machinery, so that he can repair it at a moment’s notice, that is art; and therein the artisan becomes an artist. And this feeling of something strange and foreign about the gas-producer and gas-engine, is right and wrong at the same time; it is right in the sense that there is something to be studied; it is wrong in the sense that there is nothing which a good man cannot master in a few months. Let a story point a moral and adorn a tale. In dealing with a recent customer, things came to a hitch, but I kept after him, wondering just what was holding him back. The case had all the aspects of a good proposition; the man had the need; he had the interest; he had the money; he had the engineering requirement of floor-space and head-room; he almost had the ‘sand’ to close the deal and sign the contract; but his wise common-sense held him back—he wanted to know more about it; and it came out in this way. One day he had run in on us for about the fifteenth time, and was studying gas-engine. As usual, all was going well, and I was assuring him for the tenth time that there are no ‘big niggers in the fence’ in a good gas-producer proposition, when all at once the little giant gave a sigh, a few convulsive gasps—and stopped! I was just on the point of explaining that the plant had just the same proportion of ‘little niggers in the fence’ as the same quantity of machinery anywhere else; and I was mentioning the sparking attachment as the first thing that one would look at in such an emergency. Well, we got up and strolled out to the engine-room. The engineer (who works up on the third or fourth floor) had not yet arrived, but came in shortly after us. My customer turned to me and said, "Well, we couldn’t stand for this kind of thing; our daily paper would be ancient history tomorrow, if our printing presses should stop this way. I suppose that it will be an hour or two before you get her started up again." "Oh, no," I replied. "It will be started up in a few moments," and it was. He decided to stop and see the engine started; it was only a broken spring on the jump-spark apparatus. The engine was started in five minutes, and my customer went away, but not before he had decided to close the contract. In his case, as in the cases of thousands of others, there was hesitation leaning on ignorance, ignorance of the small but vital details that someone must know; and taking the story for what it is worth, it shows that there is a certain familiarity that must come before real success will follow. Are the manufacturer, the superintendent, and the progressive man going to hold back? Are they going to defer, and defer, just because there is something that they must learn, not only from the books, but also from experience? For answer, see what is being done, in actual power-economy as compared with the best that the century-and-a-quarter of steam practice can do. From San Mateo to South Buffalo, and from Gary to Seraing, there comes the bustle of progress, progress that is too real and too busy to waste time with the timorous, but that advises us all to get ready for what is coming our way; and among the good things there are the gas-producer and the gas-engine for the large and the small manufacturer.

Bostou, April 13.

Chas. S. Palmer.

Record progress in underground driving is reported as follows, in a recent number of the South African Mining Journal: "Two miners, named Kerr and Maud, drove a connection, on the fifteenth level, between the Clement and the Rudd shafts of the Simmer Deep, a distance of 294 ft., in 61 consecutive shifts of 10 hours each, terminating with the end of April. The size of the drift was 5 by 7 ft. One white man and six Chinese were employed on each shift, and they operated three Ingersoll-Sergeant rock-drills on a bar. One round was drilled per shift, and the average footage per round was 4.92. The number of feet broken per case of gelatine consumed was 4.52, and 11.06 lb. gelatine were used per foot. Of the 61 rounds drilled, 59 had 14 holes each and two had 12 holes each. The air-pressure at surface was 80 lb. per square inch. This is exceedingly good work, and reflects the greatest credit not only on the men who drove such a remarkable footage, but also on the management of the mine and the Ingersoll-Sergeant Drill Co. Such work has certainly not been equalled on the Rand, and we believe that it stands not only as a record for South Africa but for the world. It is interesting to note that special measures were taken to cool the drift after blasting and to eliminate dust. A water-pipe was connected with the air-pipe, so that the drift could be cooled and the stuff wetted without loss of time. After blasting the 'cut' water was forced by the air into the face, so that the contractor on returning to blast the round found the drift quite cool and free from dust."
GOLDFIELD, NEVADA.—VI.

Automobiles and Gambling.

Written for the MINING AND SCIENTIFIC PRESS
By T. A. Rickard.

Mention has been made of an automobile road between Goldfield and Tonopah. The automobile is the symbol of the restless energy of these Nevada mining districts. In a bygone time men went forth to explore in sailing ships; in Mexico the mule typified transport; in the old West the patient little burro has been the mainstay of the prospector; in the North, the dog-team and the reindeer aided the mineral explorer; in Western Australia we used to ride on camels across the desert in which rich gold deposits were discovered; but in modern Nevada the mechanical genius of the age has given man a method of locomotion more swift and more flexible than any beast of burden. All the explorer needs is gasoline, instead of fodder or water. At Goldfield, gasoline costs 39 cents per gal. in cans, and 30c. in tanks. Early in the development of Tonopah, Goldfield, Rhyolite, and Manhattan the problem of rapid transit was solved by an automobile service connecting the important camps. The 28 miles between Tonopah and Goldfield has been made in 35 minutes. The usual time was 50 minutes. The regular fare used to be $6. The automobiles had three seats and carried 9 passengers apiece. In going over a bit of the old road, on the occasion of a visit to the Daisy mine, I asked Mr. C. Walter Geddes how the road was made. The automobile road between Goldfield and Tonopah was made by a stage company organized by L. L. Patrick, formerly of Leadville.

First, the sagebrush was cleared by dragging a piece of T-rail placed at right angles to the line of the road. Then ruts were marked by taking an automobile over the cleared ground; along those ruts two heavy chains were dragged behind an automobile to establish a track. Another method is to take a scraper or go-devil, somewhat after the fashion of a snow-plough; this is dragged by 8 or 10 horses, so as to uproot the sagebrush and throw loose stones and other obstructions to either side. Then a double chain or pipe (6 to 8 in. diam.) is dragged over the ground; this makes parallel ruts, serving as a track of the correct gauge. The passage of the automobiles soon makes an excellent road, but after a while bumps or ridges are formed in the ruts. These rilles are of doubtful origin; some impute them to the vibration of the engine; it is probable that the traction or slip of the rear (or driving) wheels, or more probably the irregularities in tractive effort due to vibration of the sprocket-chain, causes a kick and so makes the corrugations, which gradually spoil the auto-road. When this has become a nuisance, it is customary to pull a pair of pipes along the road and smooth it. However, even with this precaution, an automobile road in the desert soon gets out of repair. Originally straight, every swave of the fast-moving machine causes a swerve from the direct line: the next machine follows its predecessor and accentuates the deviation, until the road becomes curiously serpentine, like the trails in an African forest, where the native steps aside for every fallen tree or obstructing stone, rather than clear the track and keep it straight.

The fare to Rhyolite from Goldfield (65 miles) used to be $25 for a single passenger; it is now $4.55. The railroad killed motor travel, as might be expected. Drivers of automobiles receive $8 to $10 per day, and most of them are skillful chausseurs, both to steer and to repair. Local newspapers call them 'ma-houts,' a Hindustani term borrowed from elephant service, and absurdly out of place in the desert.

To use an automobile in traveling between the mining settlements is a comparatively new departure, but the most striking use of these machines is in hastening to a new mining excitement or 'rush,' so as to be early on the ground and locate a claim near the place of discovery. Even more than this, the automobile has been used in going across country, independent of any road, in order to see a new find of golden ore. For such work a machine with a high clearance is needed. Thus a party of mining men went 140 miles north of Tonopah across the sagebrush plain. The car hit a projecting rock, hidden in the brush; the front axle was bent almost double and a hole was torn in the crank-shaft case. These up-to-date explorers made a fire with sagebrush and straightened the axle by hammering it while hot with stones. The hole in the crank-shaft case was repaired with a piece of rubber, a part of a gunny-sack, the fragment of a coal-oil can, all of which was bound with baling wire. (Good old baling wire!) They made their return serenely. If they had not been able to make these repairs, their plight would have been serious indeed.

At Goldfield the horses have become accustomed to the whirring chug-chugging motor-vehicles, which were introduced almost as soon as the horses themselves. At Oroville, in California, there is a county law forbidding motorists to travel by day, and the time is coming when special roads will be built for this purpose all over the country, for the preservation as much of the macadam roads, which the automobiles are fast destroying, as of the comfort of those who do not happen to be in the motor-car. This reminds me of a visit to the copper mines of Michigan four years ago, when automobiles were new on the Keweenaw peninsula. Mr. John R. Stanton took me from Houghton to the Atlantic mine. The scenes by the roadside were like a continuous and screaming farce, threatening at times to turn into a tragedy. We met a dozen Cornish miners on horseback with tin dinner-buckets, and as soon as their steeds saw the machine there was a separation and scattering of Cousin Jacks, dinner-pails, and frightened horses among the rocks and brush such as no African lion could have effected. On the way we met farmers' wagons, country folk going to town, single horsemen, and in nearly every case there was a threatened mixing of the scenery and the wayfarers. I presume that long before this the inhabitants of the Upper Peninsula have become accustomed to the automobile.

At Schurz, on my return from Goldfield, I saw the rush to Rawhide. This new 'excitement' is 30
miles from Schurz, and the railroad station was crowded with automobiles awaiting passengers for the mines. The accompanying photograph shows how a Nevada rush is assisted by the automobile.

Last year ten or twelve men made a million or more apiece from the ore produced by the mines of Goldfield; of these, only five have retained their

wealth. The others wasted their money, speculated wildly, got caught in the panic, and so forth. Men made money fast, but they also lost it rapidly by over-reaching.

On the train when I returned from Goldfield to San Francisco, there were two young brokers in our smoking compartment, and these two explained all that there was to know about mining and the business of mining. It was obvious that to them mines were made to serve as counters in a game of brokerage-finance: they themselves were the real thing; the engineers and metallurgists, even the mine-owners, were but the frill on the edge of things. The conversation drifted to gambling-saloons and it was stated how much money these establishments made, then it transpired that the proprietors of such places lost to the brokers by playing the stock-market, and finally the brokers got cleaned out by going into a lot of wild-cat schemes that exploded at the time of the panic last October. And, of course, the public lost. So everyone lost. "Where did the money go?" asked one of the smart followers of Philistine finance. It was then that I ventured to suggest to these patrons of mining, as they deemed themselves, that the money had gone into hot air. Whatever wealth had been created by the extraction of gold from the ground was still in existence, of course, but it was the differ-

ence between the intrinsic worth of the mines and the fictitious value placed upon them by flamboyant promoters and tricksters that had evaporated suddenly. It was like the settlement at the cross-roads where they passed a $1,000,000 note from one to another and thought themselves gorgeously rich, until they tried to discount that note on the outside in the purchase of a keg of beer. In New Mexico they tell a story of two Indians who invested their earnings in the purchase of a jug of whisky, intending to start a saloon and make a fortune. They were both very thirsty, and one of them had 5 cents remaining from his savings, so being thirsty, he insisted on buying whisky from his partner. His partner then felt dry, and used the same 5 cents to buy whisky from the first Indian. The exchange was continued actively until there was no more whisky in the jug. This story belongs to Charles F. Lummis.

Gambling establishments play a prominent part in the life of the mining community, and rank with the Stock Exchange as a place for the making and maruing of a fortune. At the Goldfield Hotel the roulette wheel makes $11,000 profit per month nowadays, but this is small compared to the profits made by the leading gambling place, the Great Northern, during the boom days. Then on a capital of $100,000

| Broken Down in the Desert. |
| At Schurs, on the Way to Rawhide. |
and soon develops intoxication. The hotel bar and the roulette table, the ordinary saloon and its gambling annex, are eloquent witnesses to the force of juxtaposition. Besides, the players receive drinks and cigars free, that is, they are given by 'the house'. This tends to keep the gamblers in a half-fuddled condition. Their stupidity plus the chances of the table are enough to make the game profitable to the proprietor. There are 36 numbers, besides a zero and a double zero; thus the margin for the house is 2 in 38, or 5.26% in its favor. As in the other game of chance—that of the Stock Market—the average player will quit when he has made a small winning, but he will take a large loss before stopping; thus the big losses are always smaller than the big winnings. Many a man with a few dollars jingling in his pocket will drop into a gambling saloon and 'take a flyer'; when his pockets are empty he will go home; if he wins, he will remain until the luck turns and he has been cleaned out. Moreover, in betting on the black or red, the even or odd, the high or low, the bets of the players are apt to balance, and thus they save the liability of the house, which gets its 5.26% steadily from each play. The license fee is $75 per month per game. The dealers are paid 8% per day of 8 hours, the regular rate being $1 per hour. The proprietor has to pay interest on his bank roll, say, $50,000. He has to insure himself against robbery, which is frequent. Even today at the Goldfield Hotel, which in equipment and comfort and prices resembles a New York hotel, there is a man with a sawed-off shot-gun sitting behind a screen on a perch placed so as to command the bank-roll of the dealer at the roulette table. This savors of the frontier, as does the 25 cents for a shoe-shine and the 10 cents for a daily newspaper. The only alleviation is the fact that 'drinks' are two for a 'quarter.' When the 'thirst parlors' of a Western mining camp come down to 'two for 25 cents,' it indicates, strange as it may seem, the dawn of civilization.

By way of final comment on gambling as conducted in a mining camp, I venture to say that to bet on the red or the black is more sane than to buy shares on a margin and, upon the whole, the player at the roulette table gets a better show than the speculator on the stock exchange. Certainly, the game is far less crooked than that of the race-track and in itself is less insane. The evil of the gambling in a mining camp lies mainly in its associations, for the gambling annex stands mid-way between the drinking-saloon and the brothel. As a basis for betting, roulette has much to commend it, but as an instrument in debauching manhood it is altogether hateful.

The Japanese Imperial Iron Foundry, at Wakunuma, is unable to compete with foreign imports of steel and iron because of the higher cost of production in Japan. A sum equal to over twenty-five million dollars has already been spent on the plant. The director of the foundry states that he is awaiting the lapse of the convention tariffs in 1911, when it will be possible to impose duties on iron and steel.

**MINING IN QUEBEC.**

A review of mining operations in 1907, and of future prospects in the Province of Quebec, Canada, is presented in the annual report to the Government by J. Obalski, Superintendent of Mines. Asbestos was by far the most important mineral production, both in quantity and value. No less than 12 separate companies are mining this substance, among the largest being the Asbestos Mining & Mfg. Co., of Providence, R. I., operating at Wolfestown; and the Asbestos & Asbestic Co., whose plant is at Danville. Most of the asbestos mines are open quarries. With reference to gross value, cement, granite, bricks, tiles and pottery, limestone, mica, and lime, rank next, in the order named. Two new companies have started the manufacture of cement, making three in all, the centre of the industry being near Montreal. Of the metallic minerals, copper ranks highest, the principal producers being the Eustis Mining Co. and the Nichols Chemical Co., both in the Capelon region, Sherbrooke county. Of the 29,574 tons of ore mined by all companies, 19,933 was treated at Capelon and the remainder shipped to the United States. The pig-iron industry, ranking next in importance, is practically under the control of two companies: the Canada Iron Furnace Co., Ltd., at Radnor, and John McDougall & Co., at Drummondville. The 10,047 tons produced required for reduction 22,681 tons of ore, 11,511 tons of charcoal, and 4300 tons of limestone. Chrome iron was manufactured during the year by three companies in the township of Coarline. A summary of the total production of all classes of minerals is presented in the following table:

Total $3,391,368

It will be noticed that the above list includes neither of the precious metals. Mr. Obalski estimates that between 1863 and 1878 about $2,000,000 worth of gold was taken from the valley of the river Gilbert, but that since then mining has been carried on irregularly and on a small scale. He also suggests certain localities in which he thinks it might be worth while to prospect for gold.

The strength of copper is materially reduced at temperatures exceeding 500° Fahrenheit.
TREASURE MOUNTAIN, COLORADO.

Written for the Mining and Scientific Press
By C. W. Pennington.

Two and a quarter miles vertically above the level of the sea, in San Juan county, Colorado, cutting the top of the dome-like spur known as Treasure Mountain, are five quartz-filled fissures of unusual width. Three have a northeast direction, and two a course of 25° north of west. Two of the northeast views lie close together, as may be seen from the sketch (Fig. 1), so that the outercrops practically form a parallelogram, having angles of 65° and 115°, respectively, and the long diagonal oriented practically east and west. The short side is 1500 ft. and the long side 2500 ft. in length.

In their relation to the containing rock, andesite, and in mineralogical composition the veins are alike. Their most remarkable characteristic in the area of the Treasure Mountain table-top is their width. This varies greatly, but in no observed case is it less than 50 ft. between walls. Since one of the veins, namely the Atlantic, forming the northwest side of the parallelogram is especially remarkable for its width, as also for other reasons, I use it as a type to describe the group in general.

Treasure Mountain offers peculiar difficulties to geological investigation. Situated a distance of 12 miles north of Silverton, the district is not particularly easy of access at any time of the year, and generally heavy snow-falls conceal the outercrops of the veins except during the short summer. In the month of June the curious sight may be observed of beds of wild flowers hugging the edges of the daily receding snow-banks.

Descriptions of the geology of the Silverton region and of its metalliferous veins may be found in the excellent Survey reports of Messrs. Cross and Ransome. In the present paper I take up in greater detail a description of a small portion of that field.

The Atlantic vein, as mapped by Mr. Ransome, occupies a fissure along which faulting has occurred, seven miles in length, cutting Treasure Mountain in about the median portion of its length. Farther to the southwest it is known successively as the Gold Prince and the Sunnyside. North from the Gold Prince workings, in Mastodon gulch, it crosscs a high flat and cuts the shoulder of Treasure mountain, a huge solid wall of quartz, varying from 50 to 200 ft. in width. The outerop may be followed along the nearly flat top of Treasure mountain, a distance of over 2000 ft., having a curious curve to the west going north. Breaking from the northeast slope of the mountain, the great vein may be followed down the steep slope toward the Animas river, a distance of 300 ft. At this point where the augite-andesite country of the upper mountain is underlain by the more silicious latite, the vein abruptly narrows to 10 to 15 ft. in width. Now for two miles northeast on its strike, during which the outerop descends over 1500 ft. to the Animas canyon, and re-asends into Cinnamon gulch, cutting only latite and underlying rhyolite, the Atlantic vein becomes merely a narrow seam difficult to trace. Still farther to the northeast the vein cuts Cinnamon pass into Cleveland gulch in Hinsdale county, wide and prominent. It here lies again in andesite and is known as the Isolde.

For the purpose of this paper, only passing reference to the valuable metallic contents of the vein is necessary. From the Sunnyside workings, at the extreme south end of the vein, gold, with accompanying silver, lead, and zinc, has been profitably extracted for several years. Twenty stamps were at first installed, later increased to 40, and more recently to 80. North from the Sunnyside workings, the vein was worked profitably first as the Sunnyside Extension, and has lately become known as the Gold Prince. The owners of the last named property have shown their confidence in the future of it by extensive development and the erection of a 100-stamp mill and two-mile aerial tram. On the extreme northeast end of the vein, rich gold shipments have been made from the Isolde workings.

The enclosing rock of this vein, as well as of others, above the general horizon of 11,500 ft., is dark blue pyroxene andesite. On Treasure Mountain this andesite forms a nearly horizontal series of beds, fresh and massive in appearance, 1600 ft. in greatest thickness. The andesite forms the upper portion of the great series of andesite and rhyolite flows known as the Silverton series. On the northwest side of the fissure, a fault-throw has brought the Eureka rhyolite, an underlying member of the Silverton series, opposite the andesite; in fact, the fissure filled by the Sunnyside-Atlantic vein is a great plane of faulting, called the Cinnamon fault. See Fig. 2. Mr. Whitman Cross, in the ‘Silverton Folio of the Geologic Atlas,’ says of it: ‘The fault traced for the greatest distance may be called the Cinnamon fault, since it runs for a mile or more near the head of Cinnamon creek, being marked by a very prominent quartz vein. It is traceable without question, though not continuously, across the Animas and up a ravine to the north shoulder of Treasure mountain, and into Mastodon gulch. Near its western end, at the head of Mastodon gulch, it divides, forming a plexus of white veins in much altered rock, and it has been represented as identical with the Sunnyside vein which crosses into Eureka gulch. . . . Throughout its entire extent this fault is of much structural importance, as the map shows, the down-throw on the southeast approximating 1000 feet.’

The essential point is that the country rock of this vein, occupying the Cinnamon fault, and of the other four veins referred to, is the pyroxene andesite, underlaid by lavas of more silicious habit, latite, and rhyolite successively. The fact that rhyolite is brought up by faulting to the northwest of the area in question is not important to this description, but the faulting is mentioned in order that the intensity of the original fracturing may be understood.

The appearance of the outerop of the Atlantic vein on the top of Treasure mountain resembles a wide series of alternate bands of quartz and anthracite coal. This curious sight is the result of the peculiar weathering of the layers or partings of rhodonite, which form a large portion of the gangue in the Treasure mountain veins. A section of the vein was
measured in 1906 and gave a width of over 200 ft. The vein strikes N.50°E. and dips 65° southeast. The foot-wall side is exceedingly sharply defined. The containing rock is fresh in appearance and rings to the hammer. No pyritic impregnation is visible, and there is no solfatarie decomposition. The quartz rises abruptly from the sod, the wall exhibiting slicken-sides. A zone of yellowish brown quartz containing crystals of fine galena and the decomposition products of this mineral, lies next the wall, and has a width of 20 ft. Next going southeast across the vein comes a zone 30 ft. wide of massive rhodonite, which, although weathering adamantine black on the surface, when broken is seen to be a mass of brilliant pink color, very tough to fracture. It merits the special description given below. Following comes a belt of white and decomposed quartz 60 ft. wide. The quartz, which is characteristic of all the outcrops on the mountain, varies from banded to vug-like structure, is white and lustreless on surface and generally yellow-brown on fracture. Intercalated black bands and lenses represent partings and inclusions of rhodonite. The eastern edge of this quartz zone is bordered by especially brown sugary quartz probably representing the fine galena and sulphide zone like that on the foot-wall. Next comes a still wider rhodonite parting, 50 ft. wide, separated by a dike of fine-grained blackish andesite from a quartz zone which lies next the hanging wall. The relations of the dike are not clear. It has a width of 25 ft. and is traceable only for about 150 linear feet. No similar dike appears accompanying any of the other Treasure Mtn. views, although, as mentioned below, a prominent dike of rhyolite crosses the Pacifie vein.

The hanging-wall rock consists of fresh blue pyroxene andesite, entirely fresh, as far as can be observed, from decomposition products. The analyses of the Geological Survey show this andesite to have about 58% silica content and to be rather richer in potash than andesites generally are. It is the type of volcanic rock with which nearly all of the important gold orebodies of the San Juan region are associated. It forms all the upper portion of Treasure mountain, having there a maximum thickness of 1500 feet.

Before leaving the description of the gangue minerals of the Atlantic vein, the rhodonite should be especially noted. It characterizes the vein even in the deepest workings of the Sunnyside mining, now about 1000 ft. beneath the outerop. It occurs in partings 30 ft. or more in width lying between the orebodies, and generally contains small scattered crystals of zinc-blende. Certain bands of it are sufficiently rich to form a zinc ore, which is treated separately. At the main level of the Gold Prince workings, 12,300 ft. above the sea, in Mastodon gulch, I saw in a 90-ft. cross-cut of the vein a solid wall of this rhodonite, 30 ft. wide. In this perfectly fresh state seen underground, it resembles, where powder-smoke does not obscure it, a wall of pink ice-cream. Although gold is not found in the rhodonite itself, a large development of it is regarded as favorable, as one of the peculiar shoots of rich gold ore characterizing the Sunnyside vein generally occurs adjacent to it. The prevalence of large masses of manganese oxide which characterizes many gold veins, is curiously not a marked feature in those above mentioned. Rhodochrosite forming the matrix of dendritic gold threads is a feature of an exceedingly rich and small vein of Treasure mountain known as the Golden Fleece. Rhodonite itself forms a prominent constituent of the ore of the Camp Bird vein, seven miles to the west of Treasure mountain.

A remarkable feature of the great Treasure Mtn. veins is that below the horizon of the andesite, in the latite and rhyolite underlying, they are represented by quartz seams so narrow that they are often difficult to discover. Vegetation and talus conceal the slopes of the mountain so that the actual horizon where the veins pass into the underlying rock is not visible. In the canyon of the Animas river, however, carved in the Eureka rhyolite, the important Atlantic vein is represented by little more than a fracture plane. Still farther northeast, where it again enters andesite, it becomes in Cinnamon gulch a wide and ore-bearing vein.

No hypothesis which assumes the indiscriminate replacement of country rock by the quartz and gangue material appears to be acceptable to account for the Treasure Mtn. veins. All their characteristics in the andesite, clean-cut fissures, banded and vug structure, sharp contact with the walls, imply a subsequent filling of previously open space. Yet to imagine that fissures, or rather chasms, from 50 to 200 ft. wide, remained open a sufficient length of time to be filled slowly by deposition from heated solutions appears absurd. A median theory to account for their occurrence is probably the most reasonable.

In the first place, the difference of resistance
offered by the pyroxene andesite and the more siliceous underlying lavas to the original fracturing force cannot be too strongly insisted on. I have previously described the manifestation of this in the case of the Tomboy and other lodes of Savage basin. On Treasure mountain the justice of this conclusion appears to have a spectacular confirmation. The same fissures which in the rhyolite originally existed as mere planes of slipping, were in all probability wide zones of finely comminuted rock between well defined bordering walls. Malcolm Maclaren tells me in conversation that he has observed cases susceptible of this explanation in New Zealand, where lodes traverse a series of andesites and rhyolites.

Granting that zones of comminution, the result of shattering along fault-planes, and varying from 50 to 200 ft. in width, were produced, it is not difficult to conceive that silification of the comminuted material followed. Ore-bearing solutions which deposited the gangue minerals and metallic sulphides of the veins evidently did not penetrate the walls outside of the fracture-zones to an appreciable extent. On the other hand, they did succeed in changing the entire previously shattered mass, within well-defined limits and for considerable linear distances, into bodies having every appearance of regular ore-bearing veins. As to the veins or conduits through which the enormous quantity of gangue-material now occupying Treasure mountain reached its present horizon, there are only two possible explanations. One is that the responsible solutions ascended from their source through the narrow and almost imperceptible continuation of the veins in the underlying rhyolite; another is that certain fissures of a width about the same as that of the veins, and now plugged with dikes of white glassy rhyolite, were the original channels of the ore and gangue-charged solutions. A dike of this nature about 75 ft. wide is traceable for 500 ft. along the crest of Treasure mountain. It crosses the course of the Pacific, one of the large veins referred to, although at the place of intersection the relation of the two bodies is uncertain. If, as seems probable from the outcrop phenomena, the Pacific vein cuts the dike, it abruptly changes in this crossing from a width of 50 ft. to a mere series of stringers. On either side of the dike the vein assumes its normal width.

Geological literature furnishes few descriptions of vein-quartz bodies comparable in their characteristics to those above described. So sudden a change of width when the veins pass from moderately siliceous volcanic rocks into those slightly more acid is a feature well worth the attention of geologists interested in the causes and manifestation of rock-fracturing. With reference to the San Juan region in general, it is the rule that veins of workable width in the andesite are greatly reduced in size when they pass either above or below into rocks of rhyolitic or trachyctic habit. Therefore, the distinction between the component members of the volcanic series, especially in the Silverton district, should be well recognized before extensive mining development on any given vein is undertaken.

Borax.—According to the Sydney Morning Herald: "There is a strange mountain in the Death Valley region of Nevada. It is known as Mount Blanc, and consists entirely of borax. Mount Blanc is approximately 1500 ft. high, and two miles in diameter. Frank M. Smith of Oakland owns the mountain absolutely, and thereby is said to control the visible supply of borax in the world. The market value of this borax where it lies is something more than £20 per ton. Experts estimate that the mountain has at least 3,000,000,000 tons of borax in it." This is among the things to be labeled "important if true." It reminds us of the discovery of a deposit of soapstone in Utah; it was assumed that soapstone was a substitute for soap, and in consequence the hope was held out of washing the blot (which, was not specified) from off the escutcheon of the State, adding thereto the motto: "While there is life, there is soap."

The strongest timber from a long-leaf yellow pine tree comes from the lower 20 to 30 ft. At 70 ft. the decrease in strength may be as much as 60 per cent.
SMOKE IN SMELTING WORKS.

Written for the MINING AND SCIENTIFIC PRESS
By E. H. MEESMITH.

Fumes of sulphur, lead, arsenic, and other substances in the air in such quantities as to be disagreeable or harmful, or both, are frequently found in copper and lead smelting works. This condition is extremely undesirable and is often avoidable. It would seem that a more complete realization of the opposite condition is to come from more thorough study of the subject rather than from any material increase in the elaborateness or costliness of the arrangements used to handle the smoke.

Misplaced smoke may first be divided into three classes with reference to its sources:
1. Smoke issuing from a furnace or flue elsewhere than from its proper outlet during normal operation.
2. Smoke issuing through temporary openings made for charging, barking, rabbling, and so forth.
3. Smoke given off by molten or heated materials when drawn from the furnace.

The cause of the first class of smoke is generally insufficient draft; except in cases in which the volume of the smoke is unnecessarily increased by air introduced through openings in the furnace, and those cases in which parts of the furnace or flue where the gasses are under pressure are not gastight.

Insufficient draft is due either to lack of capacity in the chimney, fan, or blower, or to the existence of defects in the smoke-duct. The latter cause is much more complex than the former and is, perhaps, the commonest cause of insufficient draft.

Some defects frequently seen in flues will be mentioned below. All of them are more or less obvious, but they seem to occur often enough to warrant discussion. In many cases, of course, their presence does not indicate any lack of thought on the part of the constructor, but rather inability from force of circumstances to do anything better.

1. Insufficient area; (a) temporary, due to presence of flue-dust or other obstruction; (b) permanent, due to smallness of flue, resulting in loss of draft from excessive friction.
2. Square bends or bends of insufficient radius, including T instead of Y connections.
3. Sudden changes of cross-section. A fluid stream will not suddenly change its area of cross-section, and hence its velocity, without loss of head. In passing abruptly from a smaller to a larger duct the stream will generally refuse to change its cross-sectional area at all except at a considerable distance from the end of the smaller duct. Large chambers are frequently placed in the line of a flue for the purpose of depositing dust. The gases will ordinarily select a path through such a chamber and pass through with but slightly diminished velocity, simply making eddies in the remaining space and depositing there part of the dust. The power consumed by these eddies reduces the draft, while the fast moving central stream carries onward much of the dust that it was desired to deposit in the dust-chamber.

Several engineers have suggested that the approaches to these chambers should be tapered. If so made, the deposition of flue-dust could not fail to be much more complete and the loss of draft greatly reduced. The dust-collecting capacity of a given length of the chamber proper would be so increased that for an equal result, the total cost of the chamber would generally be reduced. Arrangements for arresting fumes, such as Freudenberg plates, bag-houses, and so forth, of course, reduce the draft by interfering friction, but the amount of such friction can be provided for in the design of chimney or fan.

4. Leakage in flues between the furnaces and the chimney or fan often introduces an amount of air that uses up an important part of the draft-producing capacity. Leakage beyond a fan as, for instance, between fan and bag-house, does not reduce the draft, but liberates gases at the ground-level, and this may be objectionable. Additional data on rates of leakage through flue-walls of different construction are much to be desired. More extensive use of the convenient bent-walls and water-gauge method of velocity-measurement instead of the anemometer will probably be conducive to an increase of accurate knowledge of this subject.

5. Incorrect arrangements of siphons. A siphon is here regarded as any elevation or depression of the flue above or below its general level. Under certain circumstances the introduction of siphons may have a dominant bearing on the success or failure of the flue. It must be remembered that from the moment the smoke leaves the furnace it is continually cooling and therefore increasing in density. In any siphon it is evident that the density of the gases in the first leg will be less than in the second. In an elevated siphon, that is, one in which the gases in the first leg are ascending, the smoke will therefore tend to pull itself over the summit. If the effect of the difference in temperature is more than sufficient to offset the friction, the smoke when once set in motion will flow through such a siphon without any other motive power. For an exactly similar reason, a depressed siphon (one in which the gases descend in the first leg) reduces the draft. If there is a considerable length of horizontal flue between the two legs or if the second leg is but slightly inclined and therefore relatively long, it is evident that the difference between the average temperatures in the two legs will be increased and the accelerating or retarding force of the siphon will be correspondingly augmented. The writer has seen a good chimney draft annihilated by a depressed siphon of this kind.

Passing now to the second class of troublesome smoke, that which escapes from temporary working-openings in the furnace, it is clear that effective methods of handling the first class will reduce or avoid the second. Such part of it, however, as may still escape needs to be treated along the same general lines as smoke of the third class, namely, that which arises from the hot solids and liquids discharged from the furnace. We can thus make a simple classification based on the method of handling rather than on the origin of the smoke.

1. Smoke that can be confined within the furnace and flue.
2. Smoke that escapes into the outer air.

The latter remains to be discussed. In considering ways of handling the escaping smoke it will be well to keep in mind the analogy that exists between the behavior of smoke in air and the behavior of syrup in water. When not greatly diluted, smoke can be mechanically removed from the surrounding air, but when dissolved in air smoke cannot be separated by any strictly mechanical means. Thick smoke has a measure of attraction between its molecules such that if we get hold of and move part of it the rest will tend to come along. It is 'stringy.'

The dilution of the smoke increases with its distance from its point of origin or with the time during which it is exposed to diffusion, and the difficulty of catching it increases in a tremendous ratio the farther away it gets. We must therefore dispose of the smoke soon after it escapes; we can then utilize its 'stringy' properties and also make use of its greater heat to create a draft to carry it away. This argues for small hoods close to the working-openings and the receptacles into which the hot products are drawn. The less air sucked in with the smoke the better. The places where these hoods are needed are the places where the workmen employ their tools. A little study will usually reveal a way in which a hood may be made, covering and enclosing the surface of hot material so as to catch the smoke and protect the workmen from radiated heat. Such a hood, outside of which the workman stands and not under it, will more often facilitate the use of his tools than interfere. A blast-furnace tapping-hood designed by me about ten years ago accomplished these objects.

It is not to be expected that these local smoke-catching devices will be absolutely perfect, but the quantity of smoke that escapes them can be made so small that the general ventilation of the building will be effective.

This last subject needs more careful attention than has heretofore been given to it. Many industrial establishments are frustrated when the wind blows, or at least when it blows from certain directions. Uncontrolled horizontal currents blow the smoke out of its proper channels and hopelessly mix the fresh incoming air with that which should be expelled from the building. Additional openings to let in more air often makes matters worse. Ventilating monitors as usually built defeat their own object a considerable part of the time. Wind blowing into the monitor strikes the under side of the roof and swerving downward blows the smoke down to the working-floors. Instead of the customary blank openings or louvres, these monitors should in general be equipped with balanced swinging doors connected across a monitor by a rod or other device, so that when a door on one side is closed the one opposite will be open. They may be hung so that the wind will close the doors on the windward side. Air will then always leave the building through the monitor and never enter there.

Generally there should be at least one solid vertical side or partition in each direction to prevent the wind from sweeping through from side to side. In a few cases where there is much heat and little smoke and where men must work on different levels that cannot be separated by floors and independently ventilated, the wide open building may be better. But, as a rule, to compel the hot and foul air to go straight upward instead of sideways will give the best results. Plenty of fresh air is the desideratum, but when the air is not kept under control more air may mean less real ventilation. In the average smelting plant of today there is probably nothing more effective that can be done to improve the conditions under which the men work than to keep the smoke out of the air they breathe during their whole working time.

The ideas on the subject of smoke-handling here outlined were carried out in a smelting plant which I designed for the Federal Lead Co., near Alton, Illinois. This plant contains a number of Scotch-hearth furnaces and also blast-furnaces and hand-roasters. In the Scotch-hearth process as employed elsewhere the smoke was considered a serious handicap, affecting the health of the men and making it difficult to keep a proper working-force. The Alton plant in operation was free from smoke on all of the working-floors. In fact very little smoke could be detected anywhere in the buildings.

Ore in stock piles awaiting shipment is taxable as personal property, according to an opinion of the Attorney General of Minnesota.

The Prospector.

This department makes a charge of 25 cents to subscribers not in arrears and $1 to non-subscribers for each determination.

From C. E. K., Kennedy, Nevada: A gabbro with much titanite and ilmenite concentrated in nodules.

Received from R. M. B., Rollin, Siskiyou county, Cal.: No. 1, acid porphyry with some pyrite; No. 2, altered acid lava.

From D. D., Ely, Nevada: No. 1, black shale; No. 2, impure crystalline limestone; No. 3, molybdenite in granite; No. 4, malachite and chalcoite in quartz.

From C. G. G., Metaline, Arizona: A substance of no specific name which supports combustion for a short time, distills crude oil and inflammable gas, and yields under the blow-pipe a light colored glassy slag; probably a highly bituminous shale.

From R. E. T., San Antonio, Texas: Specimens too small for precise judgment in doubtful cases; No. 1, crystalline limestone impure with pyrite; No. 2, highly altered acid lava charged with pyrite; No. 3, syenite; No. 4, acid lava almost completely changed to kaolin, silica, etc.; No. 5, crystalline limestone; No. 6, garnet; No. 7, altered syenite; No. 8, weathered granite (?); No. 9, biotite-hornblende diorite; No. 10, metamorphosed rhyolite; No. 11, feldspar from pegmatite; No. 12, hornblende gabbro; No. 13, garnet-pyroxeene hornfels; No. 14, fine-grained garnet-pyroxeene hornfels; No. 15, hematite and magnetite; No. 16, hornblende andesite; No. 17, garnet; No. 18, biotite gabbro (possibly a basic diorite).
VARIATIONS IN MINING COSTS.

Written for the MINING AND SCIENTIFIC PRESS
by T. A. Rickard.

In our issue of January 4, 1908, Mr. J. R. Finlay contributed some thoughtful and suggestive observations on the estimated cost of mining as compared to the actual results obtained after years of operation. In other words, what is the true mining cost, to be taken by an engineer as a basis for estimates of future profit? In his article Mr. Finlay referred to the Bunker Hill & Sullivan, one of the largest, most productive, and best managed mines in North America. He gave some figures, based on the information then available, and pointed out that besides the operating cost of $2.60, there was $3,400,000 expended in betterments and other extraordinary expenses, so that the total cost (on a production of 3,388,108 tons in 20 years) was really $1 more than the operating cost. The $1 per ton represented expenditures such as no engineer could have foreseen and such as every engineer would have omitted 20 years ago in his appraisal of future profits. This presented an interesting feature of the problem.

By the courtesy of Mr. F. W. Bradley, the consulting engineer and president of the Bunker Hill & Sullivan Mining & Concentrating Co., we are enabled to present detailed data which in effect give the complete story of operations at this representative mine. The tabulated statement given herewith is well worthy of careful study. It represents a great deal of laborious compilation and covers operations for a period of 22 years—from May 1886 to April 1908. The average contents of the ore have varied astonishingly little—in itself the mark of profitable mining on a big scale. During the 22 years the silver assay has ranged from a maximum of 5.99 to a minimum of 4.61 oz. per ton, and during the same period the lead content of the ore has varied from 295 to 214 lb. per ton, that is, from 14.75% to 10.7%. Moreover, the ore in reserve appears to be of almost identical character, for it is estimated to contain an average of 4.82 oz. silver and 11% lead.

Next we come to the extraction. In the first 6 years, the yield was 92.9% of the lead and 99.5% of the silver, because a small tonnage (3236 tons per month) was mined, and the sorting, handling, and concentration were carried to a fine point. This supposition is confirmed by the relatively high operating cost, which was $4 per ton, as against $2.27 at the present time. Moreover the cost of shipping, smelting, and marketing (including loss in smelting) per ton of product shipped was $42.69, as compared to $20.88 at the present time. In the next period, lasting 8 years, the extraction diminished so that it was only 80.7% of the lead and 71.9% of the silver. Apparently the first concentration mill had been enlarged, for the output increased to 11,627 tons per month, as against 3236 tons in the first six years. The operating cost dropped $1 per ton, and of this saving 27 cents was in the mill, for the cost of concentration had become 35 cents, as against 62 cents previously. General expenses also show even a bigger decrease, namely, 36 cents, as against over 94 cents heretofore. The total operating costs decreased $1 per ton in this second period, but even this was only a fraction of the economy introduced, for the retribution in betterments averaged $2.40, and the saving in shipping and smelting expenses no less than $5 per ton, so that the total costs were just one-half those of the first period.

The third period lasted seven years, and marked a further growth in the operations, for the average tonnage of ore mined increased to 23,835 per month, as compared to 11,627 and 2236 tons in the two preceding periods. The assay-value remained much the same, the lead declined from 11 to 10.86%, and the silver from 5.23 to 4.61 oz. per ton, but the recovery was improved to 89% and 80%, respectively, a gain of 9% in both metals. Meanwhile the market price of lead had declined from 4.33 to 3.65 cents per pound as between the first two periods, and it had recovered to an average of 4.61 cents during the third period. But silver had declined heavily, so that while the price stood at 97.37 cents per ounce in the first period, and at 66.54 cents in the second, it had dropped to 59.64c. in the third. Despite these fluctuations, the gross assay-value of the ore in the third period was $13.23, as against $11.67 in the second, and the profits won had been helped by a decrease in the tailing-loss, from $2.56 to $1.64 per ton. All the expenses incidental to the handling of the ore were diminished, so that the total operating cost was now $2.34, as against $3 in the period preceding. Betterments were less costly, so as to save an average of 50 cents per ton, but shipping and smelting had gone up to $5.47 from $3.99. This is largely accounted for by the less number of tons mined (5.11 as against 6.27) per ton of product shipped, and is also in part due to higher freight and treatment rates following the period of business depression (1892-1897), which was included within the second period. Owing to this last factor, the total cost was 21 cents higher than heretofore, but the better yield of the ore enabled a net profit to be won $83 higher than in the preceding period; the margin of profit was $4.10, as against $1.13 seven years earlier.

The fourth period brings the record to March of the current year, and covers only 10 months. The operations had been enlarged to an output of 27,223 tons per month, as compared to 23,835 in the preceding 7 years, and the discovery of large orebodies had placed the enterprise on a splendid footing. The assay-value of the ore was slightly better, but the tailing-loss was higher, because it had proved uneconomical to make a closer saving. Owing to the extension of the workings the cost of tramming is higher, but the large size of the orebodies has permitted of a lower mining cost. The total profit is $2.95, or $1.20 less, the decrease being due in large part to a falling off in "other earnings". A large profit, classed as "other earnings", was derived from the sale of the company's holdings in stock of the Tacoma Smelting Co., in the year 1905.

In summarizing the story of the mine it will be seen that an ore averaging $13.19 has yielded $11.06,

Data per ton of all ore mined, both stripping and concentrating.

**Bunker Hill & Sullivan, Warner, Idaho.**
of which $2.94 was profit. This has been on a gross production of 3,591,880 tons mined in the 22 years. No less than 13,724,474 oz. silver and 347,726 tons of lead have been produced. Mr. Finlay’s estimate of $1 for betterments would not be far wrong except that in this item is included large outlay in the acquisition of lands, aggregating about 3000 acres, which embraced a large number of mining claims, adding greatly to the available ore-resources of the company. Furthermore, a large proportion of the outgo charged as betterments consisted of expenses incident to litigation necessary to quiet title to important orebodies under the law of the apex. This might be a condition which any company would be obliged to confront, but in this case the circumstances were peculiarly fraught with legal difficulties which led to a long and bitter contest. The record shows that betterments averaged 80 cents per ton in the 22 years, ranging from a minimum of 43 cents to a maximum of $3.40 per ton. It remains to add that the estimate for the future is conservative, the ore being valued at $11.65, with a tailing-loss of $1.87, so that the net yield is expected to be $9.78 per ton. The period of construction is nearly over, for only 30 cents per ton is allowed for betterments, but the output is figured at 40,000 tons per month, so that any cost of improvements is distributed over a wide base. The entire record is most notable and is well worthy of close study, and should prompt the managers of other mines to contribute data of a similar kind.

**Guanajuato produced** from its mines $3,998,569, from September 1, 1907, to March 31, of this year, and there were expended $2,765,924 in development and equipment during the same period, according to a message of Gov. Obregon Gonzalez to the Guanajuato legislature. The ore milled amounted to 288,637 tons. There were 168 denouncements filed, covering 2585 pertenencias, or 6385 acres, of mineral land, and during the six months from September 1, 1907, to February 29, 1908, there were 111 denouncements filed, covering 1582 pertenencias, or 4649 acres. This shows a decrease in the number of denouncements, but is explained by the fact of the recent financial stringency. There were exported 19,662 tons of concentrate and ore, with a value of $1,560,057. The bullion produced from September 1, 1907, to March 31, 1908, by the different mills was as follows:

**Hawaiian coal imports**, during 1907, from the United States amounted to only 5836 tons, as against 137,000 from Great Britain and her colonies. Of the latter, 116,000 tons came from Australia.

**HYDRAULIC FILLING OF DAM.**

Written for the Mining and Scientific Press

By Donald F. Campbell.

The building of a dam for a small reservoir of 2,000,000-gal. capacity was recently accomplished by the use of a small giant, fed by a 4-in. centrifugal pump. The water was available under a 40-ft. head, and by means of a direct-connected 30-hp. motor the pressure was increased to 45 lb. per sq. in. A No. 1 giant having 2 and 21½-in. nozzles was used, costing complete $70. The consumption of water was 425 gal. per min. The work was continued about 15½ hr. per day and was finished in 80 days with 5 to 7 men working with one team. The power used was 18,500 watts, and 3200 lb. of powder was necessary. The total cost of constructing the dam, which contained 7600 cu. yd., was $2600. The material washed down was selected from the reservoir site, so as to increase its capacity. The rock was a decomposed porphyry, in which holes could be bored by the giant, of sufficient depth to be used for blasting with black powder. The method adopted was as follows: Two nozzles were built on the edges of the dam-site and the debris washed down and allowed to flow inward. In this way the gravel and sand were mixed, and the fine had a tendency to collect at the middle of the dam, while the coarse formed a good protection to the outside of the dam. The fill referred to was made exceptionally wide, so that the capacity of the reservoir could be increased at a later date. The resulting dam was well packed, and the natural deposition of the fine material in the centre, and coarser stuff on the outside only required a slight riprapping of rocks to complete an economic and efficient dam.

**Tellurium** is not fully oxidized to the di-oxide in the crucible assay of telluride ores, forming lead tellurate in the slag, as generally conceived, but is shown by Sydney W. Smith (Bull. Inst. Min. & Met.) to be decomposed at a red heat. He suggests that the reaction of litharge with tellurium is represented by the equation,

$$2\text{PbO} + \text{Te} = \text{Pb}_2\text{O}_4 + \text{TeO}$$

The return of tellurium to the lead button might then be represented by the reversal of this reaction at higher temperatures, since it has been shown that the reaction itself does not take place after silicates have been formed. The tellurium may be almost wholly removed from the lead button by ‘soaking’ it at a temperature of about 800°C. (a fairly bright red heat) in a pot or scoriator, for 30 minutes, covered with an ample amount of litharge. Mr. Smith has found differences in the gold obtained from ‘soaked’ and unsaked buttons of more than 3 per cent.
PLACER DREDGE MACHINERY

VICTOR DREDGE OWNED BY THE DREDGING DEPARTMENT OF THE ORO WATER, LIGHT & POWER COMPANY, OROVILLE, CALIFORNIA.

The Bucyrus Company has furnished four-fifths of all the successful Placer Dredges now operating in the United States and Alaska.

STEAM SHOVELS FOR MINING WORK.

The iron mines of Sweden, the copper mines of Spain, the tin mines of Siam, and the gold mines of Australia are being worked by Bucyrus Steam Shovels.

Mining Plants

This view was taken during construction of the 100 STAMP DESERT MILL at Millers, Nevada. The ore bins and batteries are here shown; the bins being almost completed, while the mortars are just being set on the concrete battery blocks. In front of the stamps can be seen the Huntington Mills (used for regrinding) which are just being set.

We constructed and completely equipped this mill and handed it over in operating condition. Its operation and design are fully described in the October 19th issue of this Journal.

We undertake the COMPLETE CONSTRUCTION and EQUIPMENT of mills, cyanide plants, rock crushing plants, samplers, smelters, etc., IN ANY LOCALITY, assuming all risks connected with construction. We are also specialists in PUMPING and POWER PLANTS, having equipped the largest power plants on the Pacific Coast.

We are DEALERS in MINING MACHINERY and EQUIPMENT for POWER PLANTS. Write us for Prices.

The Wilfley No. 3 Slime Table
FULLY COVERED BY UNITED STATES AND FOREIGN PATENTS.

The most efficient and practical machine for concentrating slimes and finely divided particles of mineral.

Large Capacity
Simple of Adjustment
Mechanically Perfect

CORRESPOND WITH OUR NEAREST HOUSE.

59 Second Street, San Francisco: C. I. Glassbrook, Agent.
The Behrend System

Of Dry Concentration
Is Ideal and Economical

The Behrend Dry Concentrator is a portable and very durable machine, requiring only \( \frac{1}{2} \) horse power to operate. Capacity 8 to 15 tons per day, according to sizes of material under treatment, averaging about 12 tons.

Will recover 80 to 90 per cent of values; is applicable to a wider range of ores and minerals than any other system; requires no skilled labor.

Makes clean separation of zinc and lead sulphides. Works equally well on all sizes from 8 to 100 mesh, and saved the slimes.

Unrivalled as a clean-up machine in placer work, recovering the black sand, gold and platinum.

The usual dust conditions peculiar to dry concentration are entirely eliminated.

Mining Engineer.
101-2 Central Bldg., Los Angeles.
Code: Bedford McNeill.

MURRO, C. H.,
Mining Engineer.
Nome, Alaska.
Code: Bedford McNeill.

NAHL, ARTHUR C.,
Mining Engineer.
Tucson, Alta, California.

NEILL, JAMES W.,
Mining Engineer.
169 Pierpoint St., Salt Lake City.

NEITZEL, KARL,
Consulting Engineer.
Mining and Metallurgical Engineer.

NICHOLS, HORACE G.,
Mining Engineer.
Manager The Ymir Gold Mines, Ltd.
Ymir, British Columbia.

NICHOLS, RALPH,
Consulting Engineer.
Special attention given to designing and erecting plants for cyanide and slime treatment.
94 North Lake Street, Aurora, Illinois.

NICHOLSON, FRANK,
Consulting Engineer.
300-310 Miners Bank Bldg., Joplin, Mo.

NICHOLSON, HUDSON H.,
Consulting Engineer.
1005 Boulevard Bldg., Chicago.

NOURSE, C. F.,
Civil and Mining Engineer.
61 Crocker Bldg., San Francisco.
Present address: Kythlim, Perm. Govt., Russia.

NOYES, WILLIAM S.,
Mining Engineer.
819 Mills Building, San Francisco, Cal.

OLCOTT & CORNING,
(E. E. Olcott, C. R. Coring),
Mining and Metallurgical Engineers.
25 Wall St., New York.

ORDONEZ, EZEQUIEL,
Mining Geologist and Engineer.
Many years experience in Mexico.

OVERSTROM, GUSTAVE A.,
Consulting Engineer.
University of Utah, Salt Lake City.
Specialty: Concentration of Ores.
Mill and Smelter Construction.

PACKARD, GEORGE A.,
Metallurgical and Mining Engineer.
Wakefield, Mass.
Boston office, 60 Congress St.

PACKER, O. H.,
Mining Engineer.
Room 82 Mills Building, San Francisco.

PALMER, CORTLANDT E.,
Mining Engineer.
230 Wall Street, New York.
Gen'l. Mgr. Guarjuate Development Co.
Cons. Engineer American Smelters' Co.
Code: Bedford McNeill.

PARKER, RICHARD A.,
Consulting Mining Engineer.
218 Boston Bldg., Denver.

PARRISH, S. F.,
Mining Engineer.
14th Floor, Union Trust Bldg., Los Angeles.

The number of Risdon Dredges in Alaska has increased rapidly since the first installation on 40-Mile River. The successful operation of Risdon Dredges in El Dorado River, Stewart River, Walkers Fork, Bonanza Basin, Hope, 40-Mile, and Nome has proved the superiority of this system.
Every part of every detail, in so far as weight, strength and capacity are concerned, is designed to meet any demand, no matter how severe. Whether you drive a CAMERON at the greatest attainable speed or so slowly you can scarcely detect any movement, each stroke is complete. Full working capacity is thus secured with the utilization of the minimum amount of steam.

A careful comparison of the maintenance cost of a Cameron Pump with that of any other make will show a considerable difference in favor of the Cameron.

This is due entirely to superiority of design, accuracy of construction, unusual strength, simplicity of working parts, and their complete protection.

Efficient and constant service is the real essential of a pump, and in this the CAMERON PUMPS excel.

At the beginning, our sole object was to produce a pump absolutely reliable under all working conditions, and when this was accomplished to our satisfaction we proceeded to build a line covering all pumping requirements.

You will find reliability the paramount feature of all CAMERON PUMPS.

Our Latest Catalog, Edition “R,” is a Valuable Reference Book for Pump Users, and is sent only on request to Managers, Engineers and Pump Men who are interested.

A. S. Cameron Steam Pump Works
FOOT OF EAST 23rd STREET, NEW YORK.
THE SOLUTION OF

Metallurgical
... Problems ...

Virginia City, Nevada, Plant of Chas. Butters & Co.,

Where the peculiarly difficult metallurgical problem obtaining remained unsolved until the first box of 100 leaves of BUTTERS PATENT VACUUM FILTER was installed and started, in September, 1904. One hundred additional leaves were added in the following year and have been in continual operation ever since—and the original leaves are still in service.

This plant is a pumping type, as the available site prevented the adoption of the gravity system. The slime treated is slow settling and viscous, yet the remarkable capacity of one and one-half tons of slime per leaf every 24 hours has been attained.

It is almost beyond possibility to suppose that this plant, or any one of the many installations of THE BUTTERS PATENT VACUUM FILTER, will apply to your case, but the same experienced engineers who successfully solved this difficult problem are at your service. We have a complete Filter plant in operation at the San Francisco offices, MacDonough Building, 333 Kearny Street. Anyone interested in Filtration is cordially invited to inspect this plant.

We invite your inquiries.

The Butters Patent Vacuum Filter Company

Apartado 1578, Mexico City, Mexico.
The Unqualified Endorsement of the United States Government HAS RECENTLY BEEN GIVEN THE

Word Bros. Drill Maker and Sharpener

Through their order for several of our 30-ft. and 20-ft. Drill Makers and Sharpeners for use on the Panama Canal.

ONE OF SEVERAL SPECIAL WORD BROS. DRILL MAKERS AND SHARPENERS IN USE ON THE PANAMA CANAL.

The U. S. Government specifications require "THAT ALL SUCH MACHINES SHALL BE WORD BROS. DRILL MAKERS AND SHARPENERS, OR EQUAL." That is certainly an endorsement of the claim that our machines are the most efficient, economical, greatest in capacity and longest lived.

LEYNER SHARPENING MACHINE

Sharpenes in one heat and FINISHES A PERFECT BIT IN THE MACHINE. No hand work necessary. Will do the work of ten men and do it better.

Insures accurate gauges. Steel stays sharp longer and therefore drills faster. We now use it entirely for sharpening our own steel. Will sharpen steel for any drill—solid or hollow.

Compact, light in weight, reasonable in price and absolutely satisfactory in operation.

U.S. AND FOREIGN PATENTS PENDING.
THE DAVIS CALYX DIAMONDLESS CORE DRILL

These illustrations give some idea of the work of the "Calyx" drill. The cores shown were removed by standard machines without the use of diamonds. The materials range from sandstone and soft coal to rolled steel. Most of these cores are larger than any diamond drill could cut without a prohibitive cost for diamonds. The capacity of the "Calyx" drill is for ores from 1, to 15 inches in diameter, from all reasonable depths to 6000 feet. The cost of a "Calyx" core hole of a size adapted to ordinary mine prospecting is $0.75 to $2.00 per foot. Compare this with the cost of a prospect shaft—$10.00 to $30.00 per foot—and the saving by the use of the "Calyx" drill for prospecting becomes apparent. Catalog H1.

Average Repair Bills Less than $1

for each machine sold during the past three years.

This covers all of the different types we manufacture.

Steam Turbines

Have you exhaust Steam?

If so, there is no need to increase your boiler equipment to get a greater electric power output.

Westinghouse Exhaust-Steam Turbines

may double your power-producing capacity with the steam you are now wasting. They will, in some cases, even generate more power than the primary engine. Our nearest sales office will give you full particulars regarding this latest development in Westinghouse Turbines.

ORE TESTING

Thorough tests upon ores for the determination of the best method of treatment are of the utmost importance, and if conducted on large quantities of material and intelligently prosecuted, will result in great saving of time and money in the erection of treatment plants. The larger the sample upon which the tests are made, the greater will be the probability that it will truly represent the regular run of the ore in the mine, and the more the errors due to the uncertainties of sampling will be eliminated. The abandoned and dismantled mills which dot the mining districts are witnesses of vast waste which might have been saved had the proper equipment been determined in advance by exhaustive tests.

No expenditures for milling equipment should be made without the previous determination of two facts; first, that the mine will produce sufficient ore to keep the proposed mill running to its highest efficiency; second, that the method of treatment selected is the best possible for the recovery of the values. The first can be proved by development work at the property; the second, by treatment tests of a comprehensive nature.

The Colorado Iron Works Company has recently completed what is probably the largest and most complete plant of this kind in existence, and is prepared to conduct milling tests on ores by all modern processes, on any scale. A pamphlet descriptive of this plant has been prepared, and it is desired to place a copy in the hands of everyone having mining interests.

SITUATIONS WANTED

The cost of advertising in this column is 25 cents per line of seven words per insertion. Minimum order 60 cents. All replies are forwarded to any address without extra charge.

A MINE FOREMAN

Thoroughly experienced mine foreman wishes to get in communication with reliable, established companies, working high grade silver mines. Active, aggressive worker, able to systematize and produce results. Handle men directly, getting efficiency without friction. Can handle men economically, and produce large amounts of ore for very small pay, and keep accurate cost sheets and comparative data, making of the mine a smooth running proposition. All references very satisfactory. Desires position of superintendent of a required grade. Married. Can go anywhere.

Address, Box 210, San Francisco, California.

EXPERIENCED AMALGAMATOR desires position. Also Amalgamer and Cyanide Expert. Address "Quartz," this office.

METALLURGIST wants position as manager, assistant to manager, or superintendent of copper smelter. Eight years experience in large and small smelter reduction in United States and Mexico. Good references. Will go anywhere and will be ready to start at short notice. Address Box 201, Cars Mining and Scientific Press.

MINE MANAGER and SUPERINTENDENT for engagement. All credentials from A1 mining companies; 20 years' western experience in gold, silver, copper, and mining and reduction. Address "DI," this office.

MINING ENGINEER desires management position, Western States or Mexico preferred. Twenty years experience, mining, milling, construction, copper smelting, extraction, etc. Has mind of his own; will stand strict inspection. Speaks German, English, Spanish. Address Box 54, Mining and Scientific Press.

SAY, want a Temple drill operator? Here is one on the market. Temple, care Mining and Scientific Press.

TECHNICAL MAN having four years experience, late with large copper smelter, wants position as assistant metallurgist or chemist in copper or lead smelting company. English and German. Speaks Spanish. Married. Address Box A, this office.

THOROUGHLY COMPETENT ACCOUNTANT desires position as manager, assistant to manager, or superintendent of copper smelter. Eight years' experience in smelting and extraction. Good references. Will go anywhere and will be ready to start at short notice. Address Box 200, Mining and Scientific Press.

WANTED—Position as manager or superintendant of mine, preferably of developed properties, by man with varied experience in the United States and Mexico. Can bring own assay outfit for gold, silver, lead and copper. Address Box 205, this office.

NOTICES OF RECENT PATENTS

Among the patents recently obtained through Dewey, Strong & Co., Scientific Press United States and Foreign Patent Agency the following are worthy of special mention.

SPARK ARRESTER.—No. 990,993; June 16, 1905, E. R. Minkler, Fresno, California. This invention relates to an apparatus which is designed as an attachment for the exhaust man- stacks of boilers for engines, or like purposes, in which, either by an ordinary or a forced draft, employed, of such a nature as to tend to cause the spark and spatter to enter the chimney. A spark-receiver may be designed as a cone, or in other shape, as desired.

SYRINGE.—No. 990,990; June 16, 1905, A. E. Macdonald, San Francisco, California.

This invention consists in the combination of a fluid, in a tube connected therewith and having spray openings in its outer end, a valve in the outer end of the tube beneath said spray openings, and a means for intermittently extending return passage upon each side, and means for closing the return passages and adapted to vary the inlet therefor, said means comprising a hood inclining the tube and passages, and slidably mounted on said tube, and valve-controlled passages connecting the inner and outer portions of the hood, with the interior of the fluid-forcing means.

BUILDING MATERIALS.—No. 990,974; June 16, 1905, J. C. Fitzsimmons and J. V. Chown, Oakland, California.

The object of this invention is to provide a cheap, practical, fireproof slab, which shall be of such a nature that, when laid upon a floor, shall have a surface capable of withstanding a fire when burning coal ashes, or the like, which is especially adapted and useful for laying into a plaster-board, and which can be nailed on to the studding like an ordinary board.

EXCAVATING AND LOADING DEVICE.—No. 990,541; June 16, 1905, E. F. Baldridge, South San Francisco, San Francisco, California.

The object of this invention is to provide a device for conveniently carrying, excavating and loading purposes, whereby the earth, sand, gravel, etc., is dumped into a bin or vehicle in one operation, and by a single stroke. The scraper is provided with a self-actuating feature; the scraper hooking on to the scraper rails, the operator holds the handle tight to prevent its tipping forward.

DIVIDEND NOTICE

SAN FRANCISCO SAVINGS UNION

N. W. Cor. California and Montgomery St.

For the half year ending June 30, 1905, a dividend has been declared at the rate per annum of four and one-quarter (41/2) per cent on term deposits, and of three and one-half (31/2) per cent on ordinary deposits, free of taxes, payable on and after Wednesday, July 1, 1905. Depositors are entitled to draw their dividends at any time during the half year. If a dividend not drawn will be added to the deposit account, becoming a part thereof and earn dividend from July 1st.

LOVELL WHITE, Cashier.

DIVIDEND NOTICE

THE SAVINGS AND LOAN SOCIETY

161 Montgomery St. corner Sutter St., San Francisco.

Closed the hair of dividend account on May 12, 1905, a dividend has been declared at the rate of 4 per cent per annum on term deposits and of 3 per cent on ordinary deposits, free of taxes, payable on and after Wednesday, July 1, 1905. Dividends not called for are added to and bear the same rate of interest as the principal from July 1, 1905.

W. M. BOSTON, Cashier.

Want a Position

At $1000 to $10,000 per year?

$500 per day is all it costs to keep your record on file, fully investigated, readily available to any employer, who may inquire for such a man as you. We send hundreds of positions to every one that comes to your notice. Ask yourself: Is it worth the price?

Pay for what you get when you get it.

You pay a reasonable commission after any temporary you pay pro rata according to the time you work. We get no money out of the bargain, get no money in, get nothing to show for it. We are paid only for the results we get.

Can you afford to do without us?

Send today for Professional Record Form and complete blank to:

Membership $4.00 per year.

MOORE & SCOTT
IRON WORKS

You Can't Blow Off the Bonnet Bittedg of
The Powell Union Composite Disc Valve

The patent ground joint connection between "A" and "B" and hexagon round nut "C" prevents that. The higher the pressure the tighter the grip. You don't need red lead or mastic steam tight after you have taken it apart for inspection or repairs—the steam doesn't reach the threads. Plenty of strength and metal where the body might be weak.

There can only be a couple of the good points in the Powell Union Disc Valve. Your booklet tells them all.

The Merrell Portable Hand Pipe Threading & Cutting Machine

You demand simplicity, ease of control, accuracy and strength in the Pipe Threading and Cutting Machine which you intend to buy, don’t you? You do not care for a Threader that only runs a part of the time—owing to breaks and “unforeseen accidents,” do you?

We can furnish for the construction of every Merrell because we make every part ourselves. We know that this portable machine has no useless weight; it can be taken anywhere, and will work well under every condition.

It will cut and thread any size of pipe—either iron or steel—any pitch or kind of thread equally well. Its simple construction makes it possible for a boy to do the work easily, swiftly and accurately.

Why not let us send you this machine on trial—We’ll gladly take it back if it is not satisfactory?

As a first step write for our catalogue.

Also made with Spiral Tempered Brass Wire Re-enforcement in top of edge.

EDGE ABSOLUTELY CANNOT CRACK

GOODYEAR RUBBER COMPANY 550-560 Market Street SAN FRANCISCO
Write for Prices, Belling, Packing, Hose, Samples and Full Particulars.
There are about seventy-five pump builders in the United States. Of these but very few seriously attempt difficult mine pumping installations. Of these few nearly all have copied, as closely as possible, the JEANESVILLE "Anthracite" design, which is still another proof that JEANESVILLE leads. There is, however, something more than design necessary to make the most reliable mine pump. JEANESVILLE has also the know-how due to thirty-five years of practical experience.

One Eclipse Drill Sharpener

Makes, Shapes and Sharpens 30,000 Drill Bits per month at the Portland Mine, Victor, Colo., in two eight-hour shifts per day with four men—two operators and two helpers. The ECLIPSE makes, shapes and sharpens Hammer Bits equally as well as the largest size steel, and is guaranteed to do more and better work than any other machine made. It has replaced other makes in the Cripple Creek and Cœur d’Alene districts and other parts of the world. If you contemplate purchasing a drill sharpener and want the best, get the ECLIPSE. We will demonstrate to you anywhere at any time that this machine is properly named ECLIPSE.

INCORPORATE IN ARIZONA COSTS LESS THAN ELSEWHERE
Advantages are Worth Thousands

No franchise tax in Arizona. No stock subscriptions required before incorporating. Any kind of stock may be issued and paid up in cash, services or property. Transact business anywhere. Stockholders exempt from company liability. No public statement required and no books need be kept for public inspection anywhere if incorporated in Arizona. President Stoddard was for years officially in charge of incorporating business and is resident agent for many thousand companies. All blanks, laws, by-laws, and particulars free. Companies incorporated on receipt of reasonable deposit on account and telegram stating name, capital, shares, and authorized debt.

Reference—Any bank in Arizona.

STANDARD BOOKS OF UTILITY

Dredging for Gold in California
BY
D'ARCY WEATHERBE
Member of the Canadian Society of Civil Engineers.

220 PAGES—$4.

Fully Illustrated with Diagrams, Drawings, and Photographs.

This valuable book on an important branch of mining practice has been prepared by an engineer well equipped for such work. Mr. Weatherbe is a conscientious writer, a graduated civil engineer, and a careful observer. To all those engaged or interested in dredging this treatise will prove invaluable. There is no book to compete with it.

STANDARD BOOKS OF UTILITY

THE FIRE ASSAY OF GOLD, SILVER, & LEAD IN ORES & METALLURGICAL PRODUCTS
BY
LEONARD S. AUSTIN
Professor of Metallurgy and Ore Dressing
Michigan College of Mines

88 PAGES—$1.

Illustrated with drawings of appliances necessary in a modernly equipped assay office.

The pages of this book are intended to cover determinations of the precious metals (silver and gold), and of lead, according to methods quite commonly recognized in the Rocky Mountain States as suited to ores and products containing these metals.

There are many books on Assaying, but none are so well calculated to serve as a ready reference for the assayer, eliminating the confusion often experienced when more than one method of determination is given.

PUBLISHED BY
THE MINING AND SCIENTIFIC PRESS.

Hints on Amalgamation AND The Care of Gold Mills.
By W. J. ADAMS.

NEW EDITION WITH ADDITIONAL NOTES.
POCKET EDITION—FLEXIBLE LEATHER COVER.

120 PAGES—$2.

A reference book of actual Gold Mill Practice as determined by an experience of twenty years. Written in language that can be understood by all.

This book appeared in 1899. The first edition was soon exhausted. The constant demand for the book caused the Mining and Scientific Press to obtain the rights for a new edition which now appears in a more pleasing and convenient form.

A GUIDE TO
TECHNICAL WRITING

By T. A. RICKARD
127 Pages—$1.

This little book is intended to help those who wish to write clearly on technical subjects. The author has long been considered an authority on the use of English in technical writing and has devoted much time during the past four years in the preparation of this work. Mr. Rickard has had an unusual opportunity to secure the data and examples necessary in the compilation of the vast amount of information offered.

A prominent educator in one of our largest Universities wrote us, after receiving the book: "It should be in the hands and its contents in the head of every writer on geological and mining topics. I shall certainly be glad to recommend it to students."

The New Continuous Leather Belt
MARKS A NEW ERA IN BELT MAKING.
The old methods of leather belt manufacture have evolved nothing better than a product which spells for the belt user expense and trouble. Short lap sections, improper methods of stretching, laps and plies and the promiscuous use of the gusset pot never produced an efficient belt.

ROBINS LAMINATED LEATHER BELTING
is made from independent continuous units cut in strands of full roll lengths from the finest selected oak tanned belting butts. The strands are laid to gauge and the width determines the thickness of the belt when they are laid on edge and laminated together. Every Strand is stretched independently to the full elastic limit, guaranteeing a belt which is practically non-stretchable. The strands are bound together to form the complete belt by a method which renders it the most powerful and compact power transmitting medium in existence.
NO LAPS, NO PLIES, NO CEMENT—Joined endless upon the pulleys with a neat and simple splice which holds the gauge balance and strength intact.
A REVELATION TO THE BELT USER.
Write for Circular No. 6 giving detailed description.

WHILE you are standardizing, why not begin at the beginning and call it standardization, not standardisation, as is done by the Institution of Mining & Metallurgy. Most of us pronounce the s like the last letter of the alphabet in unconscious avoidance of excessive sibilants. American usage has adopted standardization; why not begin standardization with standardization?

THE CALUMET & HECLA copper mine, in Michigan, was commonly supposed to have a life of thirty-five years before the dip of the conglomerate lode would pass beyond the side-lines of the property. The surprising statement is now made by the president of the company, Mr. Alexander Agassiz, in testimony given in the case of A. S. Bigelow versus Calumet & Hecla Mining Co., that the ore reserves will be exhausted in fifteen years. The testimony further revealed that the value of the surface equipment of this great mining company is not less than $15,000,-000. The salvage on such of this as could be removed would amount to less than $4,000,000. The timber in the mines is estimated at over a billion feet, board measure, and the annual consumption is thirty million feet, equivalent to the stumpage of approximately 1500 acres of ordinary timber-land.

The Greene-Cananea Copper Co. has passed through so many vicissitudes of management, mis-management, and re-organization, so many things have been done that should not, and so many left undone that would have been a comfort to the stockholders if conscientiously carried out, that questions spring to the lips whenever announcement is made of new projects or contemplated campaigns. Recently a trial-run of the new installation was promised; now it is stated that two furnaces are being blown in as a preliminary step toward a general resumption of operations. One-fourth of the concentrator is running, the ore-beds are being filled, and a small output of ore is coming from the mine. The copper-market is certainly not an invitation to present production, but inactivity is detrimental to equipment, and to prestige. The most hopeful thing in the situation is that Mr. L. D. Ricketts stands for metallurgical and engineering competence of an order that will win success if able management can achieve it.

ATTENTION may fitly be drawn to the formation of a committee at Johannesburg with a view to co-operation in making experiments in connection with metallurgical improvement. According to our contemporary, The South African Mining Journal, this committee will represent eight of the principal groups and will consist of Messrs. E. J. Way, H. C.
Behr, W. A. Caldeeott, A. M. Robeson, S. H. Pearce, W. Betty, E. H. Johnson, J. F. Cooke, A. Heyman, E. Farrar, C. B. Kingston, and W. L. Honnold. These are men known by honorable reputation elsewhere than on the Rand, and their co-operation should prove highly useful. The committee will also be prepared to examine appliances submitted by inventors and manufacturers. Eventually a central ore-testing plant and laboratory will be built, but at present the scheme is to avoid duplication of work and other unnecessary expenses incidental to the testing of processes and machinery, and the working out of metallurgical problems.

The Mining Society of Nova Scotia is an organization that has labored faithfully in behalf of the maritime Province and deserves support from the people living in that portion of Canada. At a recent meeting Mr. E. Pocay Brown read a paper entitled 'How can the gold industry of Nova Scotia be assisted?' He ended by suggesting 'that Mr. E. R. Faribault be a member of this committee.' As we happen to know how earnestly Mr. Faribault has worked in the elucidation of the geology of the gold mining districts of Nova Scotia, we are of the opinion that Mr. Brown's concluding remark is a logical reply to the question embodied in the title of his paper. But a postscript may be permitted. We hold that the recognition of facts and the publication of the truth is the best aid to legitimate mining, as also it is the most effective enemy of the illegitimate business done in the name of mining. Now, it happens that in 1905 the Government of Nova Scotia engaged a mining geologist, then residing at New York, to advise the Mining Department of the Province whether the local gold mining industry could be assisted and whether the evidence available warranted any effort to do so in a generous way. An investigation was made and a report was received in due time at Halifax. What has happened to that report? If it was a truthful statement, why was it not published; if unreliable, why was it not officially damned? Perhaps it contained some information useful to those engaged in digging for gold in Nova Scotia.

The announcement that the Lucky Boy and Mountain King mines, in Esmeralda county, Nevada, have been acquired by the Chicago Exploration Company brings to mind the interesting circumstance of their discovery, in April of last year. These mines yield exceedingly rich argentiferous galena, with tetrahedrite and other copper minerals, in a silicious gangue. The vein occurs on the contact between an acid eruptive rock and limestone, along the side of a mountain seven miles southeast of Hawthorne on the stage-road to Bodie, California. As the road zigzags up the slope it crosses the outcrop of the vein no less than four times. For forty years the wheels of stage coaches and freight teams have pulverized the ore and laid the outcrop bare, but no one stopped to examine it, nor take a sample for assay. It illustrates in a forcible manner the disregard of man for the things that are near and familiar. Prospectors brave Arctic rigors and tropic fever in the search for gold; they look out across the desert and plan adventures in the face of possible famine and thirst, filled with the hope of finding riches hidden in the mysterious distant solitudes, while their horses' hoofs are revealing treasures in the highway. For 300 years the atajos of the Mexican freighters between Vera Cruz and the City of Mexico crossed the protruding out-crop of a vein which made the fortune of an inquisitive American. It pays to be inquisitive, to sharpen the powers of observation, to test for oneself. But it requires more courage to do it than most men possess. Someone is sure to laugh, and the scoffer is more powerful than the man with a gun. These two human characteristics, disbelief in opportunity close at hand, and fear of becoming a butt of ridicule by inquiring curiously into familiar objects, keep more men from wealth than the terrors of the wilderness.

A Sign of Financial Vigor.

A trustworthy evidence of the restoration of normal financial health is found in the statement by the New York Clearing House that only about $8,000,000 remains unpaid out of the $35,000,000 advanced to crippled institutions in the metropolis by the associated banks and trust companies during the recent panic. The salvation of those institutions, which would have collapsed and pulled down others with them but for such timely and royal aid, illustrates the essential solidity of industry when the financial storm-cloud broke, in spite of a widespread mania for over-speculation. It indicates that no occult economic laws had been flagrantly violated, for which the world must pay heavy penalties, but that the weakness was a weakness of confidence, the proper antidote to which was safe-guarded extension of credit, on the homoeopathic principle of like cures like. That the New York banks have rallied, while paying six per cent on these emergency loans, is a complete vindication of the soundness of the securities in which they had been dealing, which means that they represented transactions having a vital relation to commercial growth. In other words, liquidation was not necessary to realize upon the money-values represented by this paper. In addition to all this it is announced that the Clearing House has closed the account on its ledger headed, 'Amount procured for subscriptions to loans of associated trust companies.' This account represented contributions to the relief fund by institutions which were short of available cash, but which, being perfectly solvent, were able to pledge securities and utilize Clearing House certificates issued against them, in order to swell the amount required to tide over the weaker banks. On contributions provided in this manner interest at six per cent was charged by the Clearing House. The extinction of this account, taken in connection with the prompt recuperation of those institutions which for the moment were dependent on the bounty and mercy of their comrades, should certainly react as a tonic upon the financial faith of the country.
Selby Smelter-Smoke Trouble.

THE Selby Smelting & Lead Company has received an order from the Supervisors of Solano county, to discontinue the roasting of ore until such time as the Cottrell fume-precipitation plant has been successfully placed in operation, or until November, when the cessation of the trade-winds will relieve the town of Benicia from obnoxious smoke. This order, which has become immediately effective, would shortly result in the complete closure of the smelter but for the remarkable invention of Mr. Fred G. Cottrell, who is the Professor of Physical Chemistry in the University of California. This invention has so thoroughly demonstrated its practical efficiency as to lead to its adoption, and the installation should be in working order within two weeks if the necessary transformers for the electric current arrive in time. The Cottrell apparatus eliminates carbon, dust, and sulphur compounds, whether sulphurous acid or sulphuric anhydride. Thus it saves everything of value in the smoke and will prove a source of important profit.

The Selby smelter, accordingly, will not be likely to shut down, and the Company has officially announced that it will continue to receive shipments of ore, concentrate, and bullion without interruption. But for the timely completion of the Cottrell plant, however, enormous losses would have been entailed on mine-owners scattered throughout California and Nevada, as well as upon the Selby Company and its large force of employees. A remarkable feature of the situation is that the smelter, while occasionally responsible for causing discomfort to the citizens of Benicia, has been a less grievous sinner than a neighbor whose contributions to the sulphurous atmosphere in Carquinez Straits have escaped notice because of the prevalent fashion of regarding a smelter as necessarily a nuisance. Last week a useful article by Mr. E. H. Messiter on the detecting and mitigating of smelter-fume appeared in our columns. If the citizens have made actual tests, such as those there described, and had known at the same time what was going on at the Selby works, the order from the Supervisors would not have been issued. On Thursday, May 28, the Selby smelter, which is 29 miles from San Francisco, on San Pablo bay, was shut down; that is, the roasters and blast-furnaces were put out of operation, and remained idle for one whole week. Nevertheless, on Sunday, three days after the shut-down, the people of Benicia, just across the estuary, complained of the smoke from the smelter, and twenty-seven leading citizens made a formal protest. The fume annoying them manifestly came from the Union Oil Company’s refinery. On passing the Selby works on the overland train a nasty smell should not be imputed to the smelter, but to the oil refinery, which is less than a mile to windward. Its unpleasant fume usually reaches the traveler just when he is close to the smelter. The incident affords a good example of the manner in which an unfair prejudice is created against the smelters through misconceptions for which some scientific men are partly to blame.

Lawson and the Guggenheims.

It is apparently time to chronicle the passing of Lawson as a luminary from the skies of the mining world. Far from being a fixed star, it turns out that he has not even the cometary probability of returning to inflict the market with evil portent. He was only a rocket, making a vast preliminary noise before his flight, and tumbling back without even emitting a shower of colored fire. The Yukon Gold flotation was an absolute fiasco. Out of a total of 700,000 shares, only 350,000 were taken and paid for. This spells failure, and shows that the power of the financial aerobat of Boston to draw large and admiring audiences has definitely terminated. This leaves the Guggenheims with diminished prestige, and no compensating gain in ready cash. Instead of maintaining their former honorable course as leaders of productive enterprise, they chose to trade on their reputation. They must have been conscious that since the Nipissing affair even that asset had depreciated, else they could not have been driven to such an extreme as reliance on the broken reed of Lawson’s popularity. It is persistently asserted by those who cannot be ignorant of the facts that Mr. Daniel Guggenheim himself sent for Lawson and proposed the Yukon flotation. Hence the stock was not underwritten, as would normally have been the case, and Lawson is under no obligation to take the remaining 350,000 shares. Moreover, the Copper Mines Company, which was to hold the Guggenheim interests in the Nevada Consolidated, Cumberland & Ely, Utah Copper, and other companies, will evidently not materialize. The Guggenheims are minority stockholders in all of these properties, hence, in order for Lawson to successfully complete a merger, it would require the assent of a large number of individuals who would hardly agree to the plan as now proposed. These minority stockholders represent larger interests than the Guggenheims, and they have already raised such violent opposition to the scheme as to render it quite impossible for Lawson, with any hope of financial success, to exercise his option on the stock which was to constitute the basis for the holding company, particularly in view of his discredited position after the collapse of the Yukon Gold flotation. Lawson has demonstrated his inability to longer sit in the game. A trickster may not hope to show his hand and then bluff the other players. His own egotism led him into self-betrayer, and the public, knowing the truth, can no longer give him the benefit of any doubt. As for the Guggenheims, they have sacrificed confidence and respect, but they are still powerful. Their future lies with themselves. Superstition that ‘Guggenheim luck’ would attend their ventures and make mines of prospect holes is not conducive to ultimate success. Attention to the mining features of their operations rather than to the stock market, reliance on the merits of the mines rather than upon the Guggenheim halo, a rigid rule separating the engineering staff from Wall Street, and a keener appreciation of the distinction between mine and thine, will possibly rehabilitate the tarnished name.

General Mining News.

ARIZONA.

GILA COUNTY.

The Orphan Copper Co. has completed the wagon-road from Globe to its mining property and will at once commence moving the new machinery out. A force of men has been put at work cleaning out the Orphan shaft. When repairs are completed and the new hoists in place both shafts will be sunk to at least 500 ft. before any cross-cutting is done.

MOLINE COUNTY.

It is reported that the Holy Noses and the Santa Fe groups of claims, six miles south of Kingman, have been sold to a Los Angeles company, which will sink a shaft at once.—Work on the Expansion shaft has been suspended at a depth of 120 ft., because of the inflow of a large amount of water. This is not considered a calamity, but, on the contrary, is a good omen, in that an abundance of water is assured for the new milling plant which is soon to be erected on the property.

SANTA CRUZ COUNTY.

The Creston d'Oro mine, 15 miles southwest of Calabasas, has recently completed and started a 30-ton mill. The mine is controlled by an El Paso company called the Dawson Mining Co., of which O. B. Dawson is president. A force of 30 men is employed in the mine and mill.—The Red Hill adit at the Four Metals mine, in the Mohave district, has recently cut an unexpected vein. When in 440 ft., a 14-ft. orebody, which gives fair assays in copper, silver, and lead was struck. The main vein will not be reached for at least 150 ft. more. The mine manager has asked the directors for an appropriation of $50,000 for the building of a 100-ton concentrating plant.—A new hoist has recently been put in place at the Red Cloud property, in the Harshaw district, and sinking will be commenced at once. The Red Cloud is under bond to C. H. Perry, a New York man.

CALIFORNIA.

AMADOR COUNTY.

The directors of the Central Eureka mine, near Sutter Creek, have decided to re-open the mine. The shaft will be re-timbered and sunk deeper.

BUTTE COUNTY.

Graham & Braden report that they have found a rich gravel channel in the Sky High mine, near Oroville. They penned out $4000 in five days last week.

CALIFORNIA.

The Black Wonder quartz mine, situated on Blue Mtn., nine miles from West Point, reopened last week after being closed for a year. Six men are now at work running an adit and a raise.—The Easy Bird mine-ditch is being cleaned out and other work done about the property preparatory to starting up the 10-stamp mill as soon as water can be obtained from the Mokelumne & Campo Seco canal.

PLumas COUNTY.

It is reported that F. J. Standart has sold three groups of claims, near Greenville, to A. J. McCone, representing a new company. The new owners will commence operations at once and may possibly erect a reduction plant.

SHASTA COUNTY.

James Sallee has purchased the Evening Star mine of Old Diggins, and will start work at once.—A recent fire in the assay office of the Kennett smelter did considerable damage and destroyed some valuable apparatus.

TRINITY COUNTY.

Skinner, Meckel & Fields, of Weaverville, have secured an option on the Mountain Boomer mine, in the New River district, and will start a small crew of men to work at once. The property is equipped with a three-stamp mill, a 1/2-ft. Huntington mill, and a saw-mill.

NEXA COUNTY.

(Special Correspondence.)—C. A. Malin has resigned his position as superintendent of the Ironwood mine. A few men are still employed at the property pushing development work.—A rich strike is reported from the lower workings in the Empire mine. It is rumored that approximately $200,000 was taken out in a few hours with large quantities of the bonanza ore still in sight. A large force is employed and developments are being vigorously pushed.—The working force at the Jenny Lind has been reduced. The travel has not come up to expectations.—Lessons at the Mountaineer mine have leased the Sierra Queen mill to treat their ore.—The Anti-Debils people have been endeavoring to serve an injunction on Jerry Goodwin enjoining him from operating his hydraulic properties, but have thus far been unsuccessful, as Goodwin has eluded them at every point.—Lessons have secured choice blocks of ground at the Inkmarque and are in good ore.

Grass Valley, July 6.

COLORADO.

CLEAR CREEK COUNTY.

(Special Correspondence.)—Work will be resumed next week upon the Homestake group of claims, situated on Lincoln Mtn. The adit, now in 150 ft., is to be driven steadily forward to intersect the series of veins ahead. This property is being financed by Georgetown business men, with Jos. Trudeau serving as manager.—It is stated that within the next two weeks work will be resumed upon the mines of the Democrat Mtn. Mining Co. It is believed that the Kelly adit, now in 2800 ft., is to be advanced an indefinite distance. A working fund of $60,000 has been provided. Work will also be carried forward through the Molina adit, the portal of which is 700 ft. farther up the hill. A raise will be carried from the Kelly adit to connect with the workings above. The 50-ton concentrator will be put into commission, the machinery to be fed upon ores from the Boston.—It is reported, but not officially, that the holdings of the Waldorf Con. M. Co., have been transferred under a 10-year lease to a syndicate of Kansas City, Mo., capitalists. The interested parties are said to own a large zinc smelter, and

Map of Southwestern Colorado.
after having made a number of tests upon the ores showing in the various parts of the Wilcox and Tobin adits, it has been found that the product is adapted to the method of treatment there installed. It is known that in one of the veins cut by the Wilcox adit, cadmium has been found which assays about 2%.—At the local sampler it is stated that more ore was delivered, during the month of June, than at any time since the shaft of 1891. This is credited to the fact that a great many leases are at work throughout the district. It is believed that the output will be doubled during the present month.—The Mollie Bawa mine on Covode Mtn. has been taken under bond and lease by H. C. Newton and H. C. Eckel, of Denver, who are now making a number of tests upon the ores, and as soon as the proper method of treatment has been determined, will mill to be constructed. The new firm has offices at the Cooper Bdg., Denver.—Davenport & Co., leasing on the 6th level of the Gold Dirt mine, started shipments of smelting ore this week, the product being sent to the Argos smelter, at Denver. A. Thompson, leasing on the same property, is sending out from one to two carloads of 6-oz. ore weekly, a force of 15 men being employed in the stope. The Elsie group of four claims on Alpine Mtn. has been sold to A. J. Windnagel, of Georgetown, who is now forming a company for the development of the property and expects to have work under way within 30 days. The consideration was not made public.—Work is to be resumed upon the Bernhardt group of claims, Green Lake Mtn. The adit, now in 250 ft., is to be driven ahead.—A 4-in. streak of high-grade ore has been struck on the hanging wall of the drift being run on the North Star vein, East Argentine. Tests made show values of 20 oz. gold and 9764 oz. silver per ton. The ground is now being opened to prove the extent of the discovery. M. Bonham of Georgetown is owner and operator.—The McClellan Mtn. M. & M. Co. has resumed work on company account, the contract held by W. M. Graves having been completed. A shaft was reached a few days ago which shows scattered ore, but no driving has yet been done. It is believed that the vein is the Gold Coin, but until a survey is made, this will not be known for a certainty.—The La Moe adit of the Charter-Raton M. & M. Co. is being driven steadily forward, having reached the 1150-ft. mark. The heading is still in vein matter, but the hanging wall will probably be reached in a few days. This is believed to be the true vein, and upon the surface, makes on excellent showing, a considerable amount of high-grade ore having been mined from the shaft workings.—Work is now under way upon the Drummond group of claims, Columbia Mtn. The machinery has been overhauled and placed in condition and the winze is being watered. This winze is to be sunk 75 ft. deeper, and the adit will be driven ahead. This property is held under bond and lease by the Golden Glory T. M. Co.—A number of stockholders from Chicago of the Georgetown T. Co. were in camp this week to decide upon plans for the work that is to be done in the future. They were accompanied by R. B. Sigafus of Denver, inventor of the boring machine that bears his name. This machine, which is now in the process of manufacture at Milwaukee, Wis., is to be given to the Georgetown T. Co., on the portal of which is situated on Columbia Mtn. Mr. Sigafus expects to have the equipment in Georgetown some time during the present month. G. D. Parks of this place is manager of the company.

Georgetown, July 5.

DOLORES COUNTY.

The large hoist which was moved from the railroad switch at Coke Ovens, up on the Mendosa, last fall will soon be taken to its destination at the Emma mine, where it will be put into service.—The Pre Patria mill of the United Rico Mines Co., which has been undergoing repairs for some time, was started last week and is now grinding steadily on ores from the Atlantic Cabin mine.—Work was resumed during the first of the week on the Bluebell group, in Burnett gulch, the snow having melted away so that the adits are now accessible. Edward Baer & Sons, who own the property, contemplate doing considerable mining this summer both in Burnett gulch and in Silver Creek gulch, where they own the Fourth of July group of claims, on which a good grade of copper ore has been discovered.

LAKE COUNTY.

The Granite tunnel, which is being driven into Yankee Blade hill north of the town of Granite, is fast approaching the first known vein on its line. It is expected that this point will be reached some time during the next month. Some ore has already been removed from the property, but no shipments have been made.—The management of the new Garfield tunnel has decided to cut a station some distance from the portal, and install there the plant machinery which is being built. This will do away with the necessity of erecting additional surface buildings, and will in the end, it is claimed, be cheaper.

SUMMIT COUNTY.

The success by the new mill of the Blue Flag Co. has resulted in a determination to double its capacity. In addition to milling facilities a compressor and machine drills are being installed. The company has been making continuous shipments of high-grade concentrates for the last 10 months.

TELLER COUNTY.

The production of the mines in the Cripple Creek district for the month of June was 64,150 tons of a gross valuation of $1,302,520.—The Prince Albert Mining Co., of which H. H. Hand is the president, is engaged in installing a compressor and complete plant of machinery preparatory to driving the adit on the property. The bore will be driven a total distance of 1300 ft.—The Roosevelt deep drainage tunnel is now in a total distance of 5080 ft. Progress during June amounted to only 187 ft., due to extremely hard rock with the heading lately entered.—Richard Roeloff has taken a lease on the Lonacoping property, on the west slope of Beacon hill at Cripple Creek, and will install new machinery.

IDAH0.

SHOSHONE COUNTY.

(Special Correspondence).—The principal feature of the past week in the Coeur d'Alene was the signing of a lease between Monarch Mining Co. and the Coeur d'Alene North Fork Mining Co. The lease covers the whole of the former company's property and is for a period of two years, embodying at the same time an option to purchase the property for a cash payment of $175,000 and 350,000 shares. One of the terms of the lease provides that the Coeur d'Alene North Fork company shall discharge an indebtedness incurred by the Monarch company since January last, amounting to about $17,000. The leasing company agrees to expend not less than $10,000 in the development of the property during the remainder of this year and not less than $20,000 in 1909. The Monarch company is to get 10% of all returns on ore shipped, and in the event of the North Fork company exercising its option to purchase, the proceeds from the ore shipments are to be applied toward the cash payment. Development work on the property is not to cease for more than 60 days during any six months of the lease.—An investigation into the affairs of the Snow Storm mine, one of the big dividend payers of the Mullan district, is about to be demanded by the independent stockholders. It is claimed that since last March the mine has been shipping from 500 to 600 tons per day to the smelter. At the existing price of the copper market it is estimated that the returns on this cannot be less than $6 per ton, which would make a daily profit of $3000. An attorney is to be appointed and a statement of the application of this money will be demanded.—An extraordinary statement has been issued by D. E. MacKinnon, the manager and promoter of the Amador mine, concerning which there was such a scandal. This statement forms a general denial of all charges made against MacKinnon and embodies in full a report of one
of the engineers who recently reported the property worthless. The report referred to is dated November, 1903, and is to the effect that there are enormous bodies of ore in the mine, concluding with a general defense of contradiction and congratulations of those who hold stock. MacKinnon requests that he be sent him proxies, but since then another statement has been issued by the directors requesting that they be withheld.—A strike of good ore has at last been made in the Neverswheat mining claim situated almost in the heart of the city of Burke. For more than 18 years John Mader has labored on this claim literally at the point of rifles. Time and time again has the claim been assailed by the people who desire to remove the bodies of ore that are more or less a menace to the town. This claim is the property of the Amazon-Dixie company, and is the property of the Amazon-Dixie company and the Natal Mining Company. The Natal Mining Company has been established by Mr. Everett, and he has now organized the company with the property which he has been working on the Amazon-Dixie property, and the Natal Mining Company has been organized, and the proposition that Mr. Everett will make is to the effect that the Amazon-Dixie company will drive a tunnel 1000 ft. in length which will tap the ore-shoot at a depth of 800 ft., from which point driving will be commenced toward the Alpine ground, through which the Amazon-Dixie vein has been traced for a distance of 12,000 ft. or more, between $18,900 and $20,000 worth of machinery will be installed by the Amazon-Dixie company at once. The largest ore-shoot ever discovered on the surface of any mine in the Coeur d’Alene mines has been uncovered in the Amazon-Dixie property. It is 9 ft. in width and has been traced to a length of over 800 ft. A one-sixth interest has been sold to Herman J. Ross of Wallace for $20,000. Wallace, July 6.

IDAHO COUNTY.

(Special Correspondence).—The Idaho Mascot, a newly located group of claims near Elk City, has reported some high-grade free-milling gold ore in a short prospect adit. This ore has been recently found after a year’s exploration induced by high-grade float found near the Del Rio property.—A strike of importance is reported from the Gold Crown mine near Elk City, where development is in progress on a short adit. The ore is free-milling with some tellurides.—The Crackerjack mine has been sold to M. J. Sweeney of Spokane for $900. It is thought he may be representing Guggenheim interests, as it is known they have been looking into this district for some time.

MONTANA.

(Special Correspondence).—Because of floods, damage to the Great Falls smelter of the Anaconda Copper Co., and washouts on railroads, the June copper production on the Butte district was less than 50% of the normal. All of the mines, with the exception of a few small ones, were closed entirely for 10 days, and some of the Boston & Montana mines were closed all month with the exception of two days. Two of the Boston & Montana properties were operated only 12 days. The Anaconda and St. Lawrence mines, the latter_looks so that the Anaconda-Montana Mining Corp., were closed 10 days by the floods, and after re-opening and operating for a few days were forced to close again by a fresh outbreak of gases from the fire that has been burning above the 1100-ft. levels of those mines since 1868. June was a remarkably disastrous month for Butte mining. The estimated production for the month was 13,159,000 lb. from 150,459 tons of ore. The various companies contributed to this amount as follows:

<table>

Totals.................. 13,159,000

The Big Eight mine, at Troy, 18 miles west of Libby, has been sold to a French syndicate for $69,000. A saw-mill has been purchased and will be installed at once, after which extensive developments will be undertaken. A concentrator will be erected and it is expected that the mill will be running early in the coming winter. John Gordon, of Troy, is interested.

Butte, July 6.

NEVADA.

CHURCHILL COUNTY.

The Mispah-Bretz lease at Fairview is putting in a 15-hp. hoist, head-frame, air compressor, machine drills, buckets, and 700 ft. of cable.

ESMERALDA COUNTY.

The Wisconsin mine, at Lida, will probably resume operations soon. A new hoist was put up and a shaft sunk last year. The main shaft on the Goldfield Daisy Syndicate’s property is being enlarged to three-compartment a depth of 400 ft. Shipments from the property will be resumed at once.—A company has been incorporated to bore for oil in the vicinity of Alkali springs, between Goldfield and Lone Min. A rig is already on the ground. The 55-ton Hathaway mill for the Nevada Empress has arrived at Tonopah. Clarence Elwell will be started and will be hauled to the mill by the railroad in the Gold Mountain district. Recent developments in the Nevada Empress mine may lead to that property entering the shipping list. Some ore, which is much richer than any heretofore found, has recently been uncovered in the lower winze. The Rogers-Syndicate lease, which expires at midnight July 11, has been making a wonderful production the last two weeks and it is estimated that from $16,000 to $15,000 per day have been taken out.

The mines of Goldfield produced 2129 tons of ore worth $157,200.—The total output of the Tonopah mines was $59,750 tons, of an estimated value of $150,750.

HUMBOLDT COUNTY.

A rich strike is reported from the Stoker lease on the Therien estate. It is claimed that many large specimens have been taken out which are literally permeated with coarse gold.—The hoisting equipment for the Seven Troughs Florence Mining & Leasing Co., operating the Har- ris lease on the famous property of the Seven Troughs Mining Co., near Vernon, arrived in Lovelock, the nearest railroad point, this week, and is now being hauled to the lease by teams. The equipment includes a 15-hp. Foss- Fulton gasoline hoist, head frame, buckets, and cars.

LANDER COUNTY.

The construction of a 400-ton smelter at Battle Mountain is now an assured fact and preparations are being made to begin the preliminary work on the plant. A number of Battle Mountain men are interested in the project, but the prime movers in the project are not known. Tom C. Parker, of Battle Mountain, is one of the local men who is interested in the enterprise.—The Austin-Hanapah Mining Co. is employing nearly 40 men on its properties at Austin. The Clifton adit is being cleaned out and re-timbered.

NIE COUNTY.

The L. V. & T. railway has announced a reduction of from 50c. to $1 a ton on ores shipped from the Bullfrog
MINING AND SCIENTIFIC PRESS

July 11, 1908.

The new electric equipment for the Gemini and the Ridge & Valley mines has arrived and will be installed at once. The shipment includes two big pumps and two hoists. One of the pumps will be put in on the 1700-ft. level of the Gemini and will handle 300 gal. per minute. The town of Eureka will celebrate the opening of the new Tintic smelter on July 24 and is planning to have a big barbecue.

The Taylor Brunton Co. will build a 600-ton sampling plant in the Tintic district. The North Cliff Mining Co. has been incorporated to develop three claims south of Silver City. The company is capitalized for 500,000 shares of a par value of 10c. each. Frank Thornberg is president.

The Mammoth mine, at Mammoth, has been closed for 10 days to allow repairs of the machinery. The shipments from the mines of the Tintic for the week ending July 3 were 75 carloads. The machine shop and sampling mill at the new Tintic smelter have been running, but only for limbering up and adjustment, although the management hopes to start sampling in earnest this week. It is now stated the furnaces will be blown in between July 15 and 20.

The new hoisting equipment for the Sioux Con. arrived recently and is now being installed. A new level will be started at the 380-ft. point.

The property of the St. Joe Mining Co. was purchased by some of the shareholders of the old company at a receiver’s sale last week. The price was $25,000, of which $5000 was paid in cash, the rest to be paid when the sale is approved by the court. The mine is in Bingham and has a mile of underground workings and some surface improvements. There is between $60,000 and $65,000 of indebtedness outstanding.

The stockholders of the American Flag Mining Co. will hold a special meeting at Park City, July 11, to ratify the issuance of bonds in a sum not to exceed $150,000, the proceeds to be used in the erection of a mill, further development, and to pay off all indebtedness of the company. It is believed that the force at the mine will soon be increased. A carload of machinery for the Nelson-Queen property arrived last week. The equipment includes two boilers and all accessories.

Looking Up Bingham Canyon.

district to Salt Lake valley points. A reduction of $2 a ton on crude oil has been made between Los Angeles and Rhyolite. — The plant of the Nevada Milling & Ore Purchasing Co., at Manhattan, commonly known as the Lemon mill, was turned over this week to Berry & Roche, of Tonopah, who have taken an option and lease on the plant. The work of remodeling the mill will begin at once and the new management announces that the stamps will again be dropping this three weeks’ time.

The Bitoff lease on the Black Jack claim has started work again on the 233-ft. level. It is the intention of the company to push the work in the north drift, at this level, as fast as possible.

WHITE PINE COUNTY.

Increased activity is reported from the Blackhorse mining district in the southeastern corner of the county. The French-American Mining Co. is one of the prime movers in the development and is making extensive improvements on its Lucky Boy property. D. A. Brown, of Boston, has recently purchased all the property of the Blackhorse Central Mining Co., including all water rights and the townsite of San Pedro. It seems assured that a mill will be built in the near future. — A strike 70% copper ore is reported from the Dolly Varden district in the Antelope mountain range just over the line in Elko county. — The Golden Ledge placer mine, at Hagan, in the Oseola district, has let a contract to sink a 100-ft. shaft.

NEW MEXICO.

The Whiskey mine, eight miles south of Hachita, has been bonded to a party of Nevada men for $40,000. A cash payment of $5,000 has been made. — The American mine, at the Old Hachita camp, is again under development. Robert Anderson has recently uncovered a shoot of high-grade zinc and silver ore on the 150-ft. level, which is over 60 ft. long. Pumps have been installed and arrangements made to do some deep mining. — The Anderson Apache Copper Co., whose property is in the Hachita district, on June 20 commenced shipping ore to the Copper Queen smelter at Douglas. Within the past year a two-compartment shaft has been sunk and 1000 ft. of cross-cutting and driving has been done.

OREGON.

The Portland Gold Hill Mining Co. has been incorporated, with a capital stock of $100,000, to operate the Standard, better known as the Kubil mine. The mine is equipped with a two-stamp mill. — Mining affairs in the Sumpter district appear to be on satisfactory basis. After completing repairs to the North Pole mill and the addition of more modern appliances, operations have been resumed and crushing will be continued. Development and mining operations are being carried on in the mine. The Columbia, a neighboring property, is also working full blast, with a more encouraging outlook than has yet been noted. The Golconda is still inactive, with no immediate prospects of an early resumption of work. The E. & E. is also on the inactive list. The Esmeralda is working its usual force, and extracting a fine grade of ore at present, with indications of greater results as further progress is made in development.

— The Great Northern gold mines, in Linn county, which at one time promised to become the best-paying property in western Oregon, were sold last week at sheriff’s sale for $8575 to J. M. Williams, of Eugene. The mines were originally capitalized at $4,090,000. — The Black Jack group of eight claims in the Red Rock district is again under development. The main drift will be driven forward to an intersection with vein No. 10, which it is believed will be reached within 250 or 300 feet.

UTAH.

BEAVER COUNTY.

It is persistently rumored that a consolidation of the Cedar and Taltman properties is being considered. While the management of the two properties do not affirm these reports, it is thought that such a deal is not unlikely.
WASHINGTON.

FERRY COUNTY.

(Special Correspondence).—The lessees of the Republic mine have executed an agreement with L. Harper, of Republic, and Wm. L. January, of Detroit, Mich., under which the vendors agree to surrender their lease and option to purchase said mine to the vendees for a sum not made public. The prime condition of the agreement binds the vendees to make the first payment on or before August 10. Another condition is that the vendees are to resume sinking the incline shaft on the Republic vein, which was sunk by the Republic Con. Gold Mining Co. to 125 ft. below the adit level. The present vertical depth below the croppings is 731 ft., and from indications, it is presumed that the rich pay-shoot, which was cut off at about 12 ft. below the adit, may be picked up by sinking deeper. Small pockets of the richest ore ever found in the mine were developed on the 600-ft. or higher adit level, the assays run over $5000 per ton. The most valuable mineral found was selenide of silver, associated with gold.—The Keller & Indiana Smelting & Development Co. held its annual stockholders' meeting at Keller June 22 and elected the directors for the following year. The company has concluded a deal for the purchase of the Manilla mine for $50,000 and made the first payment of $500. The Manilla vein is estimated to be from 85 to 100 ft. wide and is opened by two cross-cutting adits. The ore is partly iron sulphide and assays as high as 4.5% copper and 4 oz. silver per ton. The average of ore 70 ft. across the vein is reported to assay $17.16 per ton at the present average prices of copper and silver. A new wagon road is under construction for haulage of the ore to the smelter. The construction of a projected tramway has been deferred. The company expects to blow in the first furnace at the smelter about August 25. Rev. L. Boyle, of Keller, is the general manager of the company.

Republic, July 7.

OKANOGAN COUNTY.

(Special Correspondence).—The structure for the housing of the Palmer Mountain Tunnel & Power Co.'s mill shed is completed and a large force is at work installing the machinery. From the adit of the mine, drifts are being driven on several of the veins which were intersected, and the average value of the ore struck is reported by the management to be highly encouraging. From the 23rd vein encountered, at a depth of about 1300 ft., a shoot has been developed which shows considerable native gold, and the assays are above the average. As soon as the mill is completed electric power will be used for haulage in the adit.—From the Ruby mine, at the eastern base of Mt. Chupaca, seven carloads of high-grade ore have been shipped to the smelter since last spring. The Ruby vein is irregular in width, and in some places is 10 to 15 ft. wide. Monroe Harman is now at Mansfield, Ohio, consulting with the directors and leading stockholders of his company in regard to establishing a concentrating mill at the mine, the capacity of which has not yet been decided upon. There is enough ore already mined to keep a good sized mill in operation for some time. The mine has been opened on four levels, but very little stoping has been done. The Victoria, Vancouver & Eastern Railway Co. has built a spur within 400 ft. of the mouth of the adit.

Chechaw, July 7.

STEVENS COUNTY.

The Outcut, a mining property lying between the Eagle and the group of the United Copper Co., in the Chewelah district, has been taken over by the Blue Star Mining Co., recently organized. The company is fully financed and has made arrangements to pay a kickback of $15,000 and provide a fund for extensive development work.—It is probable that the smelter of the Colville M. & S. Co., at Park City, will be blown in by August 1. The concentrator for the Spokane Lead Mines Co. began operation at Metaline on June 20. It is the first in the district.

CANADA.

BRITISH COLUMBIA.

The Sunset claim, near Paterson on the Canadian side of the international boundary, has been sold to William H. Thompson of Spokane for $10,000.—The Dominion Copper Co. has resumed work at its Boundary mines after a shut-down of eight months.—Eight men are now working on the Woodburn claim of the recently incorporated Phoenix Mining, Smelting & Developing Co.—Hydraulic mining on Downie creek, on French creek, and on McCullough creek, in the Big Bend district, north of Revelstoke, will be worked this year. Fifteen men are already at work on French creek.—Work on the North Fork coal mines, near Granite Creek, Similkameen, has been temporarily suspended, some 15 or 16 men having been laid off. The coal measure there has been developed enough to show that a vast quantity is ready. Following the tonnage of ore shipped from and crushed at the mines of Roseland for the week ending June 27, and for the year to date:

ONTARIO.

The leasing system is finally being adopted in the Cobalt camp, where heretofore it has not been favored by the owners of the properties which control large undeveloped acreages. The development of Silver Leaf into one of the finest shipping properties in the camp is due wholly to the leasing of the property by F. D. Symmes, a rich contractor and engineer, who supplied the funds necessary for the proper exploitation of the mine. During the present spring a number of leases have begun operations on Peterson lake and have already developed several shipping properties. It is reported that Cobalt Central, Nipissing, and La Rose, the three companies which control the largest acreage in the camp, are considering offers to lease some of their unexplored territory for short periods. If such a policy is adopted it will bring a large amount of new capital into the camp and will hasten the development of the large mineralized area that these companies have not yet been able to work. The productive area of the camp is spreading in all directions as a result of the exploration work which is constantly going on. New veins are being steadily added to the known stores of silver. The Badger and La Rose have recently encountered rich orebodies heretofore unknown, and during the week the Cobalt Central has discovered on Lot 35 a new calcite vein carrying considerable bloom.
Special Correspondence.

LONDON.

Another Cornish mine has been offered to the public this week. Undeterred by the fall in tin and the poor state of some of the companies operating re-opened mines, Mr. Douglas Stewart has taken his courage in both hands and fairly deluged investors with prospectuses. He has spent something like £6,000 in advertising in the daily and weekly papers. For two days running there were two whole pages in the issues of several of the leading morning papers. I may say in parenthesis that the Financial News did not get what it considered its proper share of advertising, so in characteristic fashion picked holes in the prospectus and in Mr. Stewart’s method of business. In addition to all this newspaper advertising Mr. Stewart distributed two million copies of a very carefully prepared prospectus. The name of the company is the Boscaswell United Tin & Copper Mines, Ltd. The mines are on the Cornish coast in the extreme west, and adjoin the Levant & Botallack mines. The company is in the nature of a consolidation, several mines being included in the purchase. The two old Cornish firms of Pendeen Consols, Carllath Farm, Boscaswell Downs, Carllath Common, and Porterras. The ground covers over one square mile, and contains a great many tin and copper lodes, some of which extend under the sea, as in the case of the two neighboring mines just mentioned. In the old days they proved profitable, but since 1874 no work had been done on them until 1898, when Mr. Stewart came along. The work now being done has been centred on the Boscaswell Downs lode where it passes through the Trease property. A new shaft has been sunk here to a depth of 197 ft. and it is intended to drive in from the sea-shore about a quarter of a mile away to intersect the shaft at 300 ft. The old workings have been explored as far as possible, though as most of them are under water at present, not much has been done to check the reports of thirty years ago.

Mr. Stewart is a mining engineer of good connections and considerable means. He is at present a partner of the firm of Poore, Petit, & Stewart, consulting mining engineers. He has some influential men co-operating with him in the Boscaswell business. Among the directors are J. H. Collins, A. K. Barnett, and Dr. O. J. Steinhardt, while Solomon James, late manager of mines in Johannesburg, is the mine superintendent. The terms on which the flotation is made are very fair. Mr. Stewart and his friends take deferred shares as purchase price. The capital of the company is £200,000, of which half consists of vendor’s deferred shares, and the other half preferred shares, all of which are now being offered for subscription. The property would probably justify this large expenditure, and give excellent results if worked on a large scale. It is, however, impossible to hope that the whole of the money will be forthcoming. A good deal could be done in a smaller way with £20,000 working capital. The preferred shares will rank for their proportion of the profits just as favorably if only a few are allotted as if the whole block were taken up. They are entitled to 7½ per cent dividend. Then an equal sum of money is due as dividends on the deferred shares, after which the two classes of shares will divide any profits equally.

It will be seen, therefore, that, though 100,000 deferred shares are issued, they will only count as being equal in value to the number of preferred shares issued. The mine and the finances seem all right and it is to be hoped that Mr. Stewart will be successful.

A few weeks ago I wrote some paragraphs relating to the position of aluminum in this country, and I gave some particulars of the British Aluminum Co. I am now in a position to say something of the new company called the Aluminum Corporation, which was floated as recently as the spring of last year. The works in connection with this company have progressed rapidly. Those erected at Newcastle-on-Tyne started operations in March, and those in North Wales should be ready in August or September. When the company was formed the intention was to buy alumina in the open market, a policy the wisdom of which was open to doubt at the time. The Corporation has since found it absolutely necessary to secure bauxite properties and to do its own refining. Mines have been secured in the South of France not far from Marseilles, and the Corporation is erecting, conjointly with the United Alkali Co., a complete refining works. New installations are also being made with a firm that rolls copper and brass, to manufacture the Corporation’s products into wire and sheets instead of selling the metal in ingots, so that the Corporation should eventually be in a very favorable position for supplying the market.

After a lapse of eight years the Venture Corporation has issued a report and balance sheet. This promising company has always had a certain amount of mystery surrounding it, and has presented the unusual phenomenon of a practically bankrupt company carrying through some excellent deals. It was formed in 1897 as an amalgamation of a number of other companies engaged chiefly in West Australian business. The capital represented by the West Australian assets amounted to £475,437, but none of this has ever yielded profits nor has it been realizable in cash. Shortly after the formation of the company America was looked to for new properties to float, and the most important of these was Stratton’s Independence. The profits made out of the flotation were considerable at first. Just as a Hambly had been incurred for something like £400,000 among bankers and others with the object of buying out Mr. Stratton’s remaining interest, the collapse took place, landing the Corporation and its directors in a rather serious position. If the annual report and accounts, published last week, had been published a liquidation would have been necessary. The directors persuaded the shareholders to allow reports, accounts, and general meetings, to stand over until things could be straightened out. In a liquidation probably the creditors would have got nothing, so that it was just as well to let the Corporation go on. Perhaps also, and this is quite in harmony with the usual practice, the directors have given their own personal guarantees for the loans mentioned, and have to be called upon to fulfill this guarantee might have meant irretrievable ruin to them. Anyhow the company went on in silence for eight years, achieving some success, notably those of Camp Bird, Esperanza, Dolores, and Goliville Dredging. It also carried out the flotation of three first-class engineering firms as limited companies, together with other minor ventures. The debts of the company now seem to be wiped out, but it has no working capital. It is now proposed to wind up and re-construct, including in the new company the shareholders in two other companies that have worked in concert with the Venture Corporation, namely, the London & Continental Investment Corporation and the Mines Corporation of New Zealand. The capital of the new company will be £500,000 in 5½ per cent debenture stock, of which £250,000 will be paid in cash, and £250,000 will be allotted to the shareholders in the three companies will be given 23 shares of 4s. each in exchange for 100 old shares of £1 each, together with the right to subscribe for 100 new shares credited with 2s. paid on each. In this way 345,252 fully paid shares will be given, and 680,000 shares with the liability of 2s. will be offered. If all are issued, the Corporation will receive £28,000 in cash as working capital. The profits of the company have in some important business in connection with Siberian placer-mining.

During the year ended March 31, 1907, the Dharwar Gold Mines Co. secured a gross profit of £26,000. The sum of £12,600 (in scrip) was distributed and a credit balance of £2000 was carried forward, as against a debit of £2900 brought in. Cash and shares at the date of the balance-sheet totalled £26,550, including 18,400 Dharwar Reef £1 shares at par.
MEXICO.

One of the most regrettable effects of our recent financial troubles has been the continued inability of the Oaxaca Smelting & Refining Co. to raise the funds needed to put the company in shape to continue operations to a successful issue. This company was organized in Mexico City some three years ago, and it was supposed to have strong financial backing. O. F. Westland, former manager of the Aguaclerulates plant of the American Smelting & Refining Co., was made manager of the new concern, and apparently everything went rapidly and smoothly. After a year’s work preparations were made to blow in, and if I remember correctly a short trial-run was made. But there were rumors of international dissensions, of options on certain mining properties that had been counted on but not obtained, and the company soon began to back-track. There have been several reports that its finances have been straightened out and that operations would be resumed, but these were not proved by the events that followed. Now the plant is advertised for sale at auction, on July 7, to the highest bidder, by order of the Court to satisfy the foreclosure of a mortgage on the property. It is said that the bond-holders will probably buy it in, though there are rumors to the effect that both the Tezuitlan Copper Co. and the American Smelting & Refining Co. may be bidders. The location, however, seems improbable, as the former has its own plant at Tezuitlan, Puebla, not far distant, and the latter has never given much attention to Oaxaca. If outsiders were to appear as bidders for the property, it would seem most probable that it would be the Vogelseins. They have for some time been seeking a favorable opening in Mexico for a smelting-plant, and, although the Consolidated Metals Co. they have within the last two years become partners in, is badly tied up in Oaxaca, and are said to have had to take over first mortgage the San Juan-Taviche & Oaxaca railroad. In order to make something of that, they are pushing on to Taviche. It may be, therefore, that to get out even the purchase of the Oaxaca Smelting & Refining Co.’s plant by the Vogelsteins would be a good move. One of their head men, James A. Schloss, has been giving the Oaxaca business careful study for some time. The Magdalena smelter is also said to be in financial difficulties, and it is understood that suit has been brought to prevent Lloyd R. Hamer from transferring the property to the new company recently organized for the purpose of taking it over. The smelter was blown in May 28, however, after an expenditure of $50,000 or more, and there is a large stock of ore and fuel on hand. Whether the Magdalena mines are to be unwatered or not is not stated.

Lack of transportation, and the extremely low grade of the ores in the Taviche district, have always placed a damper on development there, but new hopes have arisen among those interested in Taviche. It is thought that the contemplated $150,000 mill (40 stamps with cyanide anex) contemplated for the principe San Carlos, on the Ocotalin river, may be completed by the end of the year, and that it will do custom work on the Taviche, San Martin, and other ores of near-by camps. Another hope rests on the early completion of the San Juan-Taviche railroad into Taviche. The Escuadr, San Juan, San Martin, San Francisco, and Taviche, as well as smaller producers, are co-operating in this enterprise, and the railroad, which it is believed will reach Taviche some time in September, when lower-grade ores may be handled which the wagon freight now makes prohibitive. All this has led to a renewal of activity throughout the Taviche district; the Conjo Blanco, which had cut off production because of the low price of the metals, and the sinking of the San Martin-De-Fina Mill have now been completed at an estimated cost of $28,000. The small camp of the Rosario has completed its steel head-frame and development work is being pushed vigorously; the Boston is preparing to resume operations, as is also the La Union; and at the Emmons mill, erected by N. H. Emmons (now with the Tennessee Copper Co. at Ducktown, Tennessee) some five or six years ago, alterations are being made for the purpose of experimenting with the low-grade ores of the Escuadr and San Juan de Taviche. If success be met with in these experiments it will mean a great deal for Taviche. At the San José de Gracia, adjoining the Navidad, recently acquired by the Mexican Mines-Prospet Development Co., a lead and experimental cyanide mill soon will be installed to study the treatment of its ores, of which it is said an amount valued at $300,000 has been blocked out.

NOME, ALASKA.

Spring Clean-up.—Difficulties in Exchange. — Wild Goose Pumping Plant.—‘Second’ and ‘Third’ Beach Output.—Nettie and Mabel Benches.—Wild Goose Co. — Sub-marine Beach Discoveries. — Anchor-Ice.

The mountain-like dumps of pay-dirt, which were extracted during the winter along the various Nome beach creeks, are too close to the coast, and the spring clean-up of 1908 will produce not less than $3,500,000. This is considered a conservative estimate, based on measurements of the yield of last year. The mining operators of Seward Peninsula have been busy this winter, and the gold is gradually flowing into the local banks. Much more will be shipped to Seattle and San Francisco than in former years, due to doubt of the scrip circulation still in vogue at Nome. Many of the mining men who went out last fall with certified checks from the Nome banks and had their deposits withheld, are still smarting under their hardships and are temporarily deposing with local merchants until an opportunity presents itself to ship direct to outside mines.

A visit to the various camps recently disclosed busy scenes of sluicing. Many operators have finished cleaning up their winter dumps and are preparing for renewed activity in summer work. Several big electric dredging machines are being installed on Wonder, Bourbon, and Dry creeks. The summer operations of 1908 will eclipse those of all former years, and this section of Alaska will undoubtedly produce nearly $7,000,000. Along Center creek, hardly a dozen miles distant from the spring clean-up of 1908 which was recently leased for this purpose by a new company, composed of Fleming Bros. & Hanks, Ernest Blank, the Eagle Mining Co., and Samuel & William Moore, a fire Lena is burning. This fire has been confined to the surface, from the different workings along Center creek, not less than $40,000 worth of pay-gravel.

The ‘second beach,’ the oldest of the pay-streaks, in point of discovery, which parallels the present shore-line for over twelve miles eastward from Nome, is still contributing its quota of fine beach-gold, and a number of scattered outfits thereon will clean up not less than $20,000 to $25,000. Along the south side of Snake River, lying at the base of Anvil peak, back of Nome, the famous ‘third beach line’ looms up with pay dumps that look like mountains, from which a modest estimate calculates the output at $1,500,000. The Pioneer company has employed about 150 men all winter on this product and the claims operated are Discover on Little creek, the Ault claim, Portland and Neston beaches, Standard, and Gertie. All these have heretofore been big producers and will be operated this summer by the latest equipment for economic summer-work. Practically the only dumps of any consequence, west of Snake River, on the ‘third beach,’ were those of Sullivan, Berger, and Payne, at the intersection of Sunset creek, on the Oakdale claim, where the output last year (estimated at about $3,000) was $40,000. The Three Bear Fraction and the Carson claim near Wonder creeks are sluicing up 75,000 cars of dirt, valued at $200,000. These are the properties of E. W. Johnston, of Seattle, who created such excitement last year by their enormous production.
About $250,000 will evidently be produced by the Slew-by-Over Beach Streak from dumps on Graham's discovery, by Crabtree and Wasky; the Yellow Jacket, operated by Hall and Elliott; and the Discovery, on Wonder, which is worked by Plein, Bosworth, and Clewes. Grigsby, Shea, Lowden, Grant, and White, of the Neltte bench, and Con- nor, Stewart, and Kelly, of the Mable bench, will clean up about $40,000 jointly. Sunbaec and Morris, on the Cyrus Noble claim, have taken out about 9000 tons of pay-dirt, while Hala and Webb, who have been working all winter on the Diamond L. claim, have an immense pay-dump, the value of which, jointly, will aggregate $30,000. At the intersection of Dry creek and the third beach, the richest dumps are on the Ingleside claim and the Rainy Day. Fully $200,000 is the estimated product from these for last winter's work. In that vicinity the Wild Goose Co. will clean up nearly $250,000 from the Discovery claim, which heretofore had been considered of no value. Recent purchases there by this company include the North Pole, the Happy New Year, the Sour Dough, and Leap Year claims, all of which are in the same neighborhood, though previously considered off the pay line. Including No. 9, on Otter creek, the Alta, and the Jupiter claims, it is calculated the Wild Goose's operations will aggregate fully $200,000. East of the Nome river, the third beach operations during the winter were lined up on the Lakeview, No. 7 Cunningham, the Dublin, Yellowstone, Good Hope, Iach Fracton, Sunnyside, and Sour Dough claims, all of which have out on the surface some very rich dumps that are now being shiced. The new submarine beach grows ap ace, and drilling operations have disclosed pay-dirt as continuous from Snake river northward through Nome's old graveyard far out to sea. During the winter drilling was carried on by means of portable derricks out on the ice. The new pay-streak, while generally termed the submarine beach, is really a stream wash of ancient origin, probably the Cretaceous period. It is found running north and south at a depth of 20 to 35 ft. below the present sea-level, or about 60 ft. from the surface. Strange to say, the drilling operations conducted through the ice last winter, after passing through the water, again pierced frozen ground, or 'anchor-ice,' underneath until a solid schist bedrock was reached. The gold is coarse, and nuggets are common. For summer exploitation colliers will be installed where shafts are necessary. Candle, Kongarok, and the Council districts have also been very busy this winter and will swell the winter's production of placer-gold from Seward Peninsula about a quarter of a million dollars.

** BUTTE, MONTANA.**

**June Production. — British-Butte Dredge. — Butte & Superior.**

*Barnes-King Co. — Butte & New York Mining Co. — Visit of J. Parke Channing.*

Because of the floods the June output fell 50% below normal, the production of copper from the Butte district being estimated at 12,160,000 lb., derived from a total of 150,250 tons of ore.

Although the British-Butte Mining Co. is engaged in a fight with the United States Government over title to the placer ground it occupies near Butte, it is announced that the company is preparing to begin dredging operations on a large scale. President DeHors has placed an order with the Ridal Iron Works of San Francisco for a dredge which is to cost $80,000. This will be installed by October.

The company is trying to get title to about 1000 acres of ground. So far as tested this will average 50c. per cubic yard. The dredge will have a capacity of 3000 cu. yd. per day. It will be operated, lighted, and heated by electricity, a contract for power having been made with the Madison River Power Co. The dredge will dig from a depth of 30 ft., but still greater values lie deeper, the best assays having been obtained at a depth of nearly 1000 ft. If the dredge proves successful some scheme will be devised for mining to a greater depth. A shaft has been sunk to a depth of 650 ft., and from that a core 310 ft. deep has been made without striking bedrock. At 650 ft. a cross-cut has been run east with the intention of cutting the rimrock and sinking on it. A number of cyaniding tests have been made and 96% of the gold saved. A cyaniding plant may be installed in addition to the dredge.

The work by the Butte & Superior Co. is limited at present, pending the arrival of a large new electric pump, which is expected shortly. The shaft is down 1175 ft., and it is the intention to install the pump at the 1200-ft. level. The big vein which was cut on the 1000-ft. level recently has not been explored, but will be as soon as the new pump is in place. The Lion Gulch Mining Co. has started a three-compartment shaft on its property in the Continental district, eight miles southeast of Butte.

The company is employing 20 men, most of whom are engaged in building a wagon-road from the railroad to the mining property, in order to bring in new machinery to equip the mine for deep sinking. Operations are under the management of John Hewitt, formerly superintendent of the Gagnon mine, and later in charge of operations for the Amazon-Butte Company.

The shaft of the Tualcume Mining Co. has been sunk to a depth of 1050 ft. and 1906 ft. of cross-cuts and drifts have been opened. Three stations have been cut and two veins have been prospected on the 1000-ft. level. The apex of two orebodies has been encountered in the south vein, the orebodies having a combined length of 600 ft., but the ore is not of commercial value at that depth.

Owing to the heavy June rains open-cut mining was suspended by the Barnes-King Development Co., and mining was confined to the underground workings, the faces of which have lately been in better ore. The increase in value of the ore has been gradual for several months. In April the heads—assays from the crushed ore—averaged $4.18 per ton; in May $4.25, while the first week in June the average was $4.45, rising in the second week to $6.02. The value of the bullion produced in May
was $29,346, and the company’s expenditures are understood to have been about $25,000. It is announced that the Butte & New York Mining Co., the holding company for the Butte-Milwaukee Co., has succeeded in raising money with which to resume development work on the property in Butte. The company also gives the cheerful announcement that the books are open to the inspection of stockholders. A statement of the Butte & New York Co. declares that the company is free from debt and is the owner of its mining property in fee simple. The company is thus in a position to resume the mining property which the Butte & New York Co. is developing. The latter company was organized on a majority of the stock of the Butte-Milwaukee Co. and the minority stockholders have never been able to understand their relation to the new concern, which was organized for the purpose of raising money in the East and to prevent the outstanding stock from depressing the market while the Eastern interests were selling stock to raise money. It has been announced that the Butte-Milwaukee stock would be made exchangeable for Butte & New York, but the stockholders have never been notified of it. A new three-compartment shaft on the Colonel Sellers claim, belonging to this company, is now down 700 feet. J. A. Jahn, of Milwaukee, president of the Pilot-Butte Mining Co., has been in Butte for some days directing preparations for a resumption of work on the Pilot claim. A shaft 530 ft. deep was sunk on the claim before work was stopped from lack of funds. Money has been provided and sinking is about to be resumed. The Pilot claim is situated in a fine section of the Butte district, adjoining the Elm Ores, one of Clark’s producing mines, and it lies near some of the North Butte and Butte & Superior mines. J. Parke Channing was in Butte last week looking over the properties of the General Development Co. and the South Butte Mining Co. The mineral ground owned, or claimed by the latter, is nearly all involved in litigation, and until that is settled the company does not know whether it owns any mineral deposits or not. Speaking of this disputed ground Mr. Channing said, "There is no question that we are there in paying quantities, sufficient to warrant operations on a large scale, and the clearance of title will be followed by the sinking of two large shafts. However, until the courts decide the legal questions involved it would be futile to contemplate operations." Mr. Channing is on his way to Globe, Ariz., where a 1,000-ton concentrator is to be installed at the Miami properties. He says the Miami Co. has 4,000,000 tons of 3% copper ore in sight and can make copper at a cost of 9c. per pound. Speaking of the copper situation he said: "I believe the price of copper will advance very soon. The consumption keeps pace with the progress of commercial business and manufacturing industries, and in these there is a decided improvement. The copper market is here, and there are no large stores in Europe or America. There was infinitely more copper in the country when the metal was selling at 25c. than there is today."

TORONTO, CANADA.

Serious Fire at Cobalt.—New Vein on the La Rose Claim.—Nipissing Ore-Reserves.—Geological Survey Work.—Dominion Coal Company.

Considerable loss to mining companies in the Cobalt area has been occasioned by bush fires, which for some days ravaged the northeastern portion of Coleman township. The principal losses occurred on June 28, when the buildings and machinery of several properties were consumed, the men in some cases barely escaping with their lives. The Columbus, Lumaden, Shanrock, Fisher-Eplitt, Cochran, and Columbus Development lost their buildings and plant, and in several other instances properties were saved only by the most strenuous efforts of the miners. The town of Cobalt escaped and none of the larger shipping mines were injured. Some injury was also done at the new camp of South Lorraine or Silver Centre, many prospectors losing their property.

The Standard Cobalt Mines Co., one of the subsidiary companies of the Cobalt Central, has leased 10 acres adjoining the Big Pete on the south. The lease, which is from the Halcyon Cobalt, is on the basis of 50% royalty. The period is for two years with an option for three additional years.

At the La Rose mine, Cobalt, a notable discovery, indicating the continuous richness of the property, has been made 60 ft. southwest of the main shaft at a depth of 35 ft., consisting of a blind vein, running parallel to the main vein and having a high silver content. Prof. Hidden, of Newark, N. J., who is preparing a report on the La Rose and was in the camp at the time, confirms the value of the find. The Nipissing has now a force of 302 men engaged in mining and prospecting, and the management hopes to double the amount of ore-reserves this summer. The available ore now has an estimated value of about $900,000. It will take about two months to reach the strike recently made by diamond-drilling on the Kendall vein 300 ft. east of the shaft. A nugget of pure silver, claimed to be the largest ever taken from any mine, and valued at $3000, has been sent to New York from the Nipissing property for exhibition on Wall Street. Considerable outcrops have been entered into for extensive diamond-drilling on the Hazel Jule property on Sasaingea lake, in the expectation of tapping continuations of the rich veins on the properties adjoining the Hudson Bay and the Coniagas. Work on the University claim, which was a big producer in the early days of the camp, is being resumed as a consequence of the La Rose discovery. Some high-grade ore is being taken out of the adit at the 100-ft. level. W. Hamilton Wilson, who has recently returned from the Brazilian diamond fields, is pushing development work on his properties in the South Lorraine camp, and has struck a promising caliche vein, having a good silver content. Ore shipments from Cobalt for the week ending June 27 amounted to 405 tons, from the following mines: Badger, 21; 100, 3; Cobalt, 58; Drummond, 20; McKinley-Darragh, 22; Nipissing, 31; O'Brien, 31; Right-of-Way, 30; Temiskaming, 60; Trethewey, 66; and Watts, 30 tons.

The operations of the Canadian Geological Survey have been considerably hampered this season by want of funds, owing to the delay of Parliament in making the necessary appropriations. The result has been a number of parties have been sent out, that should have started earlier in the season. Among the more important undertakings by the Survey are the explorations on the Churchill river by W. McInnes, embracing a region which may possibly be opened up before long by the Hudson Bay railway; the study of the economic geology of the Montreal river area, and its extension; and investigations by M. E. Wilson in the district north of Lake Temiskaming in Quebec province, where prospecting for gold is being steadily carried on.

There has been great activity in coal mining in Nova Scotia this season. The output of the Dominion Coal Co. for June was $47,000 tons, as against $31,900 in June 1907. For the first six months of the year the output was 1,392,419 tons as compared to 1,625,729 for the corresponding period last year.

The prosecutions which were threatened for the violation of the law regarding prospectuses in connection with Lawson's flotation of the Yukon Gold Co. have not materialized. The matter was brought to the notice of J. J. Jof, Provincial Attorney General, in the Mining Journal. The Government, however, declined to undertake a prosecution while the Provincial elections were pending. Although nearly a month has elapsed since election day, no action has been taken. There has been much complaint of the slackness of the Attorney General's department, not only in several cases arising in connection with joint-stock company-promotions which are hanging indefinitely, but as regards the enforcement of the laws where financial or political interests are involved.
SEVEN TROUGHS, NEVADA.

General Topography and Geology.—Mills in Operation.—Mazuma Hill Mining Co.—High-grade Ore.—Mazuma Mining & Development Company.

The Seven Troughs mining district is on the eastern slope of the Stonehouse range of mountains, 30 miles northwest of Lovelock, in Humboldt county, Nevada. This range has a north-south trend and is chiefly a rhylolite country, having belts or zones of andesite and basalt carrying mineralized veins. There is one principal zone of this character, and perhaps two others, not so well defined, all striking north-south along the eastern slope of the range. The principal zone is of considerable width, and contains several parallel veins on which important development has been performed. These veins have a dip of approximately 50°, and a width of two to twenty feet. The walls are andesite and basalt, and the gangue, or vein-filling, consists of quartz, talc, and schillified rhylolite, carrying gold and silver in the ratio of about one ounce of gold to one of silver. The mill work now being performed in the district demonstrates that 90% of the precious metals can be recovered by smelting. The ores contain a small percentage of pyrite, which is caught in Willey tables and vanners, making a concentrate that is high grade.

The district is marked by a series of shallow canyons which follow the crest of the range, and drain easterly to an extensive flat which separates the Stonehouse range from another range to the east. Where these canyons cross the vein formation the out-croppings are most apparent, and at these points are the original workings of several of the properties. It is in these canyons that the erosion has exposed the veins. In approaching Seven Troughs district from the east, crossing the divide between the Hunstide and Stonehouse flat, one gets a bird’s-eye view of the district, showing the parallel canyons referred to, and several of the little mining towns that mark the various centres of operation. The town of Mazuma is at the mouth of Seven Troughs canyon, and the 10-stamp mill of the Mazuma Hill Mining Co. is situated at this place. The town of Seven Troughs, which marks the location of some of the best properties, is about two miles farther up the same canyon. At the mouth of an arroyo to the south of this is the town of Vernon. The three canyons north of, and running parallel to, Seven Troughs, are known as Wild Horse, Burnt, and Stonehouse. Some important mining development is going on in Wild Horse canyon, and Burnt canyon is of interest as one of the main sources of the water-supply for the district; and Stonehouse canyon has some very valuable mining properties under development, the town of Farrell being situated there. The distance from Seven Troughs to Stonehouse canyon is six to eight miles. The principal mineral zone, above referred to, appears to extend from near Vernon in a northerly course to Stonehouse canyon and possibly beyond. It may be observed that the initial points for mining on this zone are at the interesting canyons referred to.

The district contains two 10-stamp mills, both in operation; at least 20 gasoline hoists, and it is estimated that about 200 men are at work, including the lessees. A good grade of ore has been found on perhaps 15 properties, but a brief account of the workings and characteristics of a few of the principal ones will be typical of the best in the district.

The Mazuma Hill Mining Co., controlled by John Harnan and associates, has six claims on the north side of Seven Troughs canyon, covering a considerable distance along the strike of the principal zone, which on this group consists of four or five parallel veins. The principal development consists of a 650-ft. adit-level on one of the strongest veins; a second adit, 190 ft. above this, has been driven 400 ft. on the same vein, and two pairs of stopes have been sunk on the veins each 100 ft. below the main level, and from the base of these winzes extends 400 ft. of driving on the vein. One of the winzes is used for hoisting ore to the main level, at which a gasoline hoist is stationed. Three raise connections the main adit with the upper level and all ore from the latter is passed through chutes to the main level, which is provided with tramage to the ore-bins. The vein is 20 ft. wide in places and narrows to 3 ft. in others. This company’s 10-stamp mill is said to be operating on one ore that averages $40 per ton. There are high-grade streaks in the mine which yield from $300 to $1000 per ton. The plan is to mix the different grades and mill all the material between the vein walls.

There are several leases on other parts of the group, among which are the Reagan, Prior, Chadbourn and Bradley, all of which are winzable veins that run parallel to the Mazuma’s main vein. These leases run two years and are all active, the Reagan having shipping-ore.

The Mazuma Mining & Developing Co., managed by H. C. Sandifer, has a lease on ground extending south from Mazuma hill, but on the opposite side of the canyon. They sank a 100-ft. shaft and ran a cross-cut east to one of the veins and will now sink a shaft on this vein. The Kindergarten Mining Co. has holdings that cover the series of parallel veins on the principal zone, but on the south side of the Seven Troughs canyon.

SALT LAKE, UTAH.

Silver King Consolidated Versus Silver King Coalition.—New Mill for American Flag.—Bingham Output in June.—Ohio-Kentucky at Pioche.

Notices have been sent by the United States Smelting, Refining & Mining Co. to contract-shippers, informing them that ore will be accepted again. The lead department of the smelter will be in commission about August 1, but the date when the copper furnaces will blow-in is indefinite. Only the lead section is permitted to run under the provision of the contract issued from the Federal Court to the Co., any having expended a large amount of money in the installation of new processes and devices for the elimination of the elements contained in the fumes which endanger and destroy vegetable life.

A special meeting of shareholders of the American Flag Mining Co., of Park City, has been called for July 11, at which time the matter of issuing $150,000 worth of bonds will come up for consideration. If the bonds are authorized, as no doubt they will be, the proceeds will be applied toward providing mill facilities.

The application of the Silver King Consolidated Mining Co., for an order of court permitting its engineers to survey and examine certain workings of the Silver King Consolidation mine at Park City has been granted, the former being the plaintiff in two suits filed recently charging the defendant with trespassing under development, the town of Farrell being situated there. The distance from Seven Troughs to Stonehouse canyon is six to eight miles. The principal mineral zone, above referred to, appears to extend from near Vernon in a northerly course to Stonehouse canyon and possibly beyond. It may be observed that the initial points for mining on this zone are at the interesting canyons referred to.

The district contains two 10-stamp mills, both in operation; at least 20 gasoline hoists, and it is estimated that about 200 men are at work, including the lessees. A good grade of ore has been found on perhaps 15 properties, but a brief account of the workings and characteristics of a few of the principal ones will be typical of the best in the district.

The Mazuma Hill Mining Co., controlled by John Harnan and associates, has six claims on the north side of Seven Troughs canyon, covering a considerable distance along the strike of the principal zone, which on this group consists of four or five parallel veins. The principal development consists of a 650-ft. adit-level on one of the strongest veins; a second adit, 190 ft. above this, has been driven 400 ft. on the same vein, and two pairs of stopes have been sunk on the veins each 100 ft. below the main level, and from the base of these winzes extends 400 ft. of driving on the vein. One of the winzes is used for hoisting ore to the main level, at which a gasoline hoist is stationed. The Kindergarten Mining Co. has holdings that cover the series of parallel veins on the principal zone, but on the south side of the Seven Troughs canyon.
Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Two fundamental rules for the guidance of surveyors in re-surveying of lands, other than mining claims, are these: (a) Marked lines and courses control courses and distances. (b) Monuments determine boundaries and transfer all the land included. In other words, the existence of undisputed or conclusively proven monuments, establishes the limits of a parcel of land, even though the description in the deed does not conform to the positions of the monuments. And in case some of the monuments are missing, the surveyor should remember that his survey is to determine where the original monuments were, and not where they ought to have been.

Pan amalgamation of silver ores has made no progress in recent years, since the introduction of the Boss continuous system. With the improved forms of roasting-furnaces now available it would probably be most economical to precede the actual pan-amalgamation by a chloridizing roast. The old method consisted in introducing from 6 to 18 lb. common salt and 3 to 9 lb. copper sulphate into the charge, cupric chloride being formed, which reacts with silver sulphide as follows:

\[ \text{Ag}_2\text{S} + \text{CuCl}_2 = \text{CuS} + 2\text{AgCl} \]

Only the native silver or the silver chloride are available for amalgamation with the mercury.

Clays are ultimately derived from the decay of older rocks, the finer particles resulting from this decay being carried off and deposited by streams along their channels, in lakes, or along parts of the sea-coast, or in sea-bottoms as beds of clay. In chemical composition clays consist essentially of silica and alumina, though iron oxide is almost invariably present in varying amounts, while lime, magnesia, alkalis, and sulphur are of frequent occurrence, though usually only in small percentages. The term is applied to fine-grained unconsolidated materials which possess the property of plasticity when wet, while they lose this property and harden on being strongly heated.

A placer patent conveys title to all lodes or veins the tops or apices of which are found within the patented boundaries, and which were not known to exist at the time the placer patent was applied for. If, at the time application for patent was made, any such lodes or veins were known to exist within the placer boundaries, they are excepted out of the placer patent, and may be located by any qualified locator, with 25 ft. of surface on each side of the vein. But no one has a right to invade the limits of a placer patent for the purpose of prospecting for lodes, or locating them, unless it is clearly established that their existence was known prior to the filing of the placer patent application.

Peat is a fuel of high calorific power, and is used in large quantities in many European countries for domestic purposes. As an industrial fuel it has not attained high rank, and all attempts to utilize it in America have been economic failures. The difficulties presented in the use of peat are many. The ratio of volatile combustible to fixed carbon is excessive, resulting in a tendency to flash-fire. The ash content is invariably high, ranging from 20 to 40%, so that when the volatile materials have distilled off, the proportion of ash in the residual coke is so enormously in excess of the remaining fixed carbon that it is difficult to maintain combustion of the latter until it has been consumed. Furthermore, peat as dug from its beds is always saturated, and owing to its porosity it holds the moisture tenaciously. It therefore becomes costly to reduce the percentage of water to 10%, while elimination of the water below that amount is economically prohibitive. Other fuels must be very costly before peat, even when found near the point where it is required, can be economically substituted.

If the owner of a mining claim resumes work on the last day of the calendar year, and thereafter continues with reasonable diligence to prosecute it until the fall amount necessary to protect the property from re-location is performed, the law is satisfied. No valid re-location may be initiated so long as the work is in progress. Where a group of claims is involved, the work may be done on one of the claims, if such work would manifestly and obviously tend to develop them all and the aggregate amount done after resumption is equivalent to $100 in value for each claim in the group. There is some danger, however, in confining resumption of work to one of a number of claims. The re-location of the others by an outsider would place the burden on the original locator to show, by a preponderance of evidence, that the resumption was in good faith, and that the work being done on one was obviously for the benefit of all. It would be much safer to resume work on each claim.

Plaster of paris is pure gypsum finely ground and calcined at a temperature less than 400°F. If the gypsum is not pure, or if certain materials be added, the product of the calcination is the so-called cement-plaster. If pure gypsum, broken into lumps, but not finely crushed, be subjected to a heat of about 932°F. for three or three and one-half hours, the product is the so-called flooring-plaster, and is therefore a pure plaster entirely free from water. Hard-finish plasters, known commercially by such trade names as Keene's cement, Parian cement, and the like, are the product of the calcination, at or above a red heat, of gypsum to which other substances, usually alum or borax, have been added. Plaster of paris differs physically from cement-plaster in that it is much quicker-setting. Flooring-plaster, while not utilized in England or the United States, is employed largely in Germany for floors, and gives a very hard and durable surface. The material attains this hardness only when it is protected from moisture while setting, and to obtain the maximum density it must be tamped after standing for about 12 hours. Hard-finish plasters are very fine-grained white powders, with a slow rate of setting.
Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

Cyanide Costs.

The Editor:

Sir—I was interested in the statement of Liberty Bell costs of precipitation and clean-up for the month of March, 1908, as given in your issue of June 13. The figures herewith submitted cover the same costs at the plant of the Desert Power & Mill Co., Millers, Nevada, for the month of May, 1908, and are on the same lines as those given by Mr. Moulton, not including the distributed charges of superintendence and depreciation. They may be interesting for comparison, showing the cost in different localities and under different conditions:

- Ore milled, tons of 2000 lb. 12,830
- Solution through zinc-boxes, tons $1,000
- Precipitate recovered and dried, lb. 31,572
- Bullion from precipitate, oz. 291,412
- Metal in precipitate, per cent. 71.5
- Bullion fines, gold and silver, per 1000. 972.6

COSTS.

Precipitation:
- Zinc, 23,735 lb. $5,536.26
- Cut at plant, 15,969 lb. at 9.6c $1,529.94
- Shavings, 7,764 lb. at 13.6c 1,006.32
- Cutting 15,969 lb. 141.00
- Power and supplies 222.45
- Total $2,999.71

All solution was pumped through boxes.

Clean-up and Filter-Pressing:
- Labor of cleaning and re-packing boxes. . . . $519.45
- Four clean-ups are made each month. There are 17 seven-compartment boxes, each compartment having 15 cu. ft. for zinc-space.
- Total zinc capacity, 1755 cu. ft.

Refining:
- Acid treatment of precipitates is not used.
- Drying and melting:
  - Coal, 7500 lb., at $12.44 per ton... $ 92.90
  - Coke, 31,572 lb., at $17 per ton. . 532.37
- Fluxes:
  - Flourspar, 158 lb. 8.41
  - Borax, 5454 lb. 418.34
  - Borax glass, 100 lb. 20.50
  - Soda, 2699 lb. 112.01
  - Crucibles. . . . . . . . . . . . . . . . . . . . . . 167.84
  - Labor. . . . . . . . . . . . . . . . . . . . . . . 725.55
  - Repairs and sundries 116.69
  - Power. . . . . . . . . . . . . . . . . . . . . . . 15.30
  - Total 1,928.32

Total cost. . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . $5,347.48

Cost per ton of solution:
- Precipitation $0.0558
- Clean-up and filter-pressing 0.0064

Refining
- Total $0.0660
- Refining cost per troy ounce of bullion. . . 0.0066

Labor is paid $4 per 8-hr. shift, refinery helpers $4.50 per 8-hr. shift, and two refinery men receive $160 and $145, respectively, per month.

A. R. PARSONS.

Tonopah, Nevada, June 16.

Cornish Pumps.

The Editor:

Sir—I am interested in the correspondence under the above heading that has appeared lately in your paper. For the last five years I have had a good deal to do with Cornish pumps of the old style, having four or five of them constantly at work in mines under my management in this district (Linares, Provincia de Jaén, Spain). Previous to this I had had a good deal of experience with other classes of pumps in various mines in both North and South America. Fortunately, I have never had to deal with millions of gallons of water per 24 hr., so my remarks will doubtless be of little interest to those unfortunate people who are required to deal with such exceedingly wet mines. So far I have had to tackle only from 200 to 250 gal. per minute, but this amount has had to be raised through vertical heights of from 1500 to 1900 ft., and were that amount to be doubled and the heights increased by another 1000 ft. or so, I confidently believe that my present convictions would hold good. I do not propose to present figures as to the duty and other more or less theoretical computations as to what a mine-pump should do, but to confine my remarks to what Cornish pumping engines have done and are actually doing in a district that has produced and is still supplying a large percentage of the world’s production of lead.

Linares is a district where labor is cheap and efficient, while masonry construction is cheaper than its timber equivalent in most western American mining camps. If a shed be required for the foreman’s donkey, or a prop be necessary to carry a launder over the dressing-floors, both would be built of good sound masonry. I came to the district with the belief that the Cornish pump was obsolete, that it should be replaced at the first possible opportunity by something more modern and theoretically perfect. I am now convinced that I shall leave it with the conviction that the mine manager who desires absolute freedom from pump-worries, coupled with the comforting knowledge that he can at any moment continue the sinking of his shafts, or cope with a sudden increase of water, without doing more than add a lift to his column or increase the number of his engine strokes, had better forget his prejudices and put in a Cornish pump. It is perhaps well to note here that many of the so-called failures of Cornish pumps have not been true Cornish pumps at all. Some have been German imitations or improvements; others have had Cornish pit-work with horizontal engines with crank and fly-wheel. These abominations, coupled with ignorance or neglect during installation, have done much to create the prejudice which exists today against what is really the most reliable and practically efficient of all mine-pumps.

I propose to briefly describe one or two of the oldest pumping installations in this district as typical of a dozen or more similar ones that are today doing yeoman service, and I can then safely leave it to your readers to judge for themselves what trustworthy old servants these much-abused Cornish
pumps have proved themselves to be. About the year 1861 the Linares Lead Mining Co. bought a second-hand 60-in. Cornish engine in Cornwall, and shipped it to Linares. It was erected at the Santo Tomás shaft of the old Pozo Ancho mine, and was, I believe, the first Cornish pump installed in the district. The pump continued to work until the year 1883, the shaft at that time being down to the 11th or 780-ft. level. It was also working a pump in another shaft situated a quarter of a mile distant, by means of flat rods. The western end of the mine then began to look more promising, and the workings there being deeper, they were more heavily watered. The pump was therefore moved and re-erected at Peillé's shaft. A new steam-cylinder, piston-rod, and condenser-chamber were put in. This pump is working today most satisfactorily, handling all the water from the Pozo Ancho mine from a depth of 1830 ft. There is a 60-ft. stand-pipe on top of the column at the surface, and all the mine-water is pumped up to a reservoir a quarter of a mile away from the shaft under a head of 40 ft. The length of stroke of the pump in the shaft is 9 ft., it is raising approximately 200 gal. per minute, and apparently has done so for the last 47 years in Spain, before which time no doubt its happy childhood was well employed at home. The boilers consist of two comparatively new Cornish-Galloway boilers, 28 ft. long by 6 ft., 6 in. diam., with another old one as a stand-by. The working pressure is 45 lb. per square inch, and the normal number of strokes per minute is 4½. The plunger-holes are arranged in the shaft as follows: a certain amount of water is taken into the cistern at the 1068-ft. level from the eastern section of the mine:

Total: 1380 ft.

There is an underground balance-bob, at the 930-ft. level, as well as one at the surface. The pump-rods are 12 in. square, and about 42 ft. long. One or two at most are changed every year. A rod of Spanish pine costs 90 pesetas or 18 pesos; one of foreign pine costs about 150 pesetas or 30 pesos. One of the latter will last from 15 to 18 years. The fuel burned is a long-flame soft Spanish coal, called screened Puertollano. It is a dirty coal, of second-class quality. The pumping-engine consumes 170 tons per month of this coal, which works out at about 6 lb. per horse-power per hour. The mine-water contains much lime and other substances, which form a deposit in the column and so reduce its effective diameter, the original inside diameter of the column being 14 in. There are no air-vessels or other 'fakes' in the column. The rods and poles work so quietly and smoothly that it is often difficult to realize there is a pump at work in the shaft.

A watchful Cornish foreman keeps a fatherly eye on the whole system, but a Spanish pitman at 75 cv. per day, with the aid of a little tallow keeps the whole mass moving sweetly. It is often a source of joy to the manager to watch a beautifully polished black plunger-pole make its slow, majestic, silent plunge into the stuffing-box and come to rest with that rhythmical sound that means the valves are seating nicely, and to see a little clear water ooze up through the packing, showing that it is taking in no air, the while ruminating on the fact that this process has gone on for the last half-century, and to all appearances could continue to do so for all eternity. Another Cornish pump, at work in Taylor's shaft at the Los Quinientos mine, belonging to the same company, is a comparatively modern affair. This was purchased new and installed in the year 1871, and for the last 37 years has pumped all the water from one of the most profitable mines of the district. It is a comparatively small mine, and only makes about 100 gal. of water per minute. The shaft has reached a depth of 1650 ft. The engine has a steam-

![Peillé's Shaft, Linares, Spain.](image-url)
this pump as now arranged there are some fairly high lifts; they have never given the slightest trouble from the day they started to work, and the shaft is as dry as the proverbial well. The poles are arranged as follows:

10-in. pole at depth of 331 ft. from surface equals 331-ft. lift
10-in. pole at depth of 716 ft. from surface equals 385-ft. lift
10-in. pole at depth of 1021 ft. from surface equals 305-ft. lift
10-in. pole at depth of 1328 ft. from surface equals 297-ft. lift
8-in. pole at depth of 1618 ft. from surface equals 300-ft. lift
6-in. bucket at 1650 ft. from surface equals 32-ft. lift

Total ........................................... 1650 ft.

During the 37 years this engine has worked it has only had a new cast-iron condenser-chamber; the cylinder-liner is not now in first-class condition.

One more example will serve to show the Cornish pump as compared with a direct-acting steam-pump. Some three years ago it was decided to open an abandoned mine. The shaft was about 300 ft. deep, but the lower 200 ft. was caved. It was decided to put up a Cornish pump-engine, but I wished to push ahead with the work while the engine was being erected. This engine had a 36 in. by 8 ft. cylinder. A well known type of American direct-acting sinking-pump, 14 by 6 by 12 in., was put in the shaft and operated by steam from the new Sandycroft Cornish boilers that were eventually to run the Cornish engine. The country rock was decomposed granite, so there was a lot of sand, and conditions were not favorable for pumping. That sinking-pump was running for about nine months, that is to say, it was running when it was not being repaired, or the sand being cleaned out of the valve-chambers. Some progress was made with the clearing and sinking of the shaft during the intervals, and the pump used up three tons of coal every 24 hr. In the end it wore itself out pretty badly; it also wore out the patience of the pit-men and mechanics, so that you can't talk steam pumps to them any more. When the Cornish pump started up with a 10-in. pole at the 300-ft. level, and a bucket lift for sinking, it quietly handled the water and sand at two strokes per minute, and the coal consumption went down from 3 tons to 16 cwt. per 24 hr. The shaft-sinking was completed to the 550-ft. level and driving started. The water soon doubled and trebled on us. The Cornish pump got up its gait to 7½ strokes per minute, and kept it up for 18 months with hardly a stop, and as the surrounding country was drained the water gradually fell off. Now the pump is going at a comfortable 4½ strokes per minute, and if the mine will only hold out it will continue to do so for another half-century. I have often wondered how we should have got on through that time had we been dependent upon steam-pumps. Probably the company would have been broken, and it would not have been the first mining company that steam-pumps have broken. I am beginning to think that I shall be charged with being a champion of Cornish pumps, and as you know, I am not a Cornishman, nor have I ever set foot in Cornwall. What is the alternative? Steam pumps underground are out of the question; compressed air is too expensive; a big electric installation is more expensive in first cost than its equivalent in Cornish pumps. Given a good hydro-electric supply-station, and a decent rate for the electric horse-power, there is no doubt much to be said in favor of the high-lift centrifugal pump. I believe the three-throw geared-pumps, electrically operated, are not an unqualified success. In any electric installation of pumps there must crop up the sinking problem. I doubt whether this has been satisfactorily solved by electric pumps. It must not be forgotten that reliability is economy in mine-pumps. I am not ashamed to admit, as some apparently are, that I am a champion of the Cornish system of pumping wherever the conditions are at all favorable for it.

Ernest P. Woakes.

Foothill Copper Belt of the Sierra Nevada.

The Editor:

Sir—In your issue of May 2 I find a criticism by O. H. Hershey of my paper the title of which appears above. I fear that Mr. Hershey in his proper scientific zeal, which I sincerely admire, has jumped with rather too much force. My short paper, in frank avowal, was merely a preliminary study, the conclusions drawn being based only upon facts observed in certain portions of the belt. Furthermore, to forestall the kind of criticism made by Mr. Hershey, I stated in the beginning, "In fact, the information concerning the belt under discussion is yet so slight that it is impossible to formulate any broad generalizations. Whether or not the belt possesses unity as a province of any class, metallographic, petrographie, or structural, is yet to be settled." I fondly labored under the belief that my position was thus made clear, but evidently my hopes were vain. The object of a preliminary study, such as my paper was, is two-fold. It must attempt to correlate known facts sufficiently to make possible a few definite, even if temporary, conclusions. Also it should be so written that more description by others on the same subject shall follow. The copper belt of California has long lacked such description; if Mr. Hershey and others will give us what facts they possess, our knowledge will rapidly increase. From this point of view also I appreciate the expression of Mr. Hershey's opinion.

I think it is obvious that every mine, whether in a region of fixed well known characteristics, or in one of great variability, must always be examined on its own merits. General or preliminary descriptions of mining regions are of use only as such, and no right-thinking man would be guilty of drawing final conclusions for a particular mine from them. Their purpose is to awaken interest and lead to a gain in knowledge. Hence it appears to me the "pernicious" effects of my conclusions, drawn under limitations clearly stated, do not materialize.

But it may harm nothing to glance for a moment at a few facts. Mr. Hershey would have considerable secondary sulphides northwest of Copperopolis. Calaveras and the more northern counties have produced considerable copper since the initiation of the industry, but the primary ore has been the important
one. True, rich surface ores were worked, even at Copperopolis, but these did not last long, and the various holes and prospects all along this portion of the belt show chalcopyrite near the surface, at times actually outcropping. Exception will probably be found; it would be strange otherwise. The Copperopolis deposit is unique in some of its features, but I cannot regard it as wholly so. The type of deposit is natural for the soft schists of the belt, and with no peculiar structural conditions I see no reason to so regard the deposit itself. The ore I have examined from the Cavan mine, in Mariposa county, from the 100-ft. level, was composed of seams of chalcopyrite in schist, not greatly dissimilar to the Copperopolis ore. In the group of mines near the well-known White Rock, in Mariposa county, including the Pechahontas, the original sulphides are near the surface, except at the Pechahontas itself, which has peculiar local structural conditions. But even here, with roughly a 100-ft. zone of secondary change, bottomed by rich secondary sulphides, the mine is to be made or unmade by the unaltered sulphides below. This indicates that it is wise to get the other fellow's point of view. There are hundreds of prospects north and south of Copperopolis along the belt, for the most part consisting of shallow holes and pits. There are the deeper mines as well. That much secondary sulphide ore exists southeast of Copperopolis cannot be doubted, from Mr. Hershey's descriptions. But I believe that most of these properties depend for value as mines upon the primary ore; the secondary ore may be rich, but gives out too soon. The Green Mountain mine, in Mariposa county, appears to be a good example. It was in this particular sense I used the word ore in the statement disliked so by Mr. Hershey, even limited as I was in my area of examination. I believed that this meaning was evident after my description of all the ore that I had handled, secondary and original.

As a matter of further note, every one of the conclusions drawn in my paper are as open to the criticism made by Mr. Hershey as the one chosen. But the facts were limited, as was clearly evident. Logically, therefore, the conclusion drawn must be regarded in the same light. They hold only for the area described, "from the facts presented in this paper." My mode of expression, in a desire for brevity, may have been somewhat abrupt, and if so, I willingly admit my fault. But even this, I believe, cannot alter the main conditions under which I wrote.

Mr. Hershey makes much of decrease of copper content with depth in the southern mines, accounting for this entirely by secondary sulphide-enrichment. While in no sense questioning his observations on chalcopyrite and other minerals, I can state definitely that at a number of mines south of Tuolumne county, the names of which I am not at liberty to divulge, the primary sulphide ore slowly changes with depth, the grade becoming poorer. There is yet a vast field for investigation concerning the vertical order of mineral deposition.

I think our misunderstanding indicates that we need more knowledge. Contribution to information was surely my aim in writing the paper under discussion. Lastly, I must protest against the intimation that my paper was based upon the examination of but one deposit. My legs often informed me that there probably were nearer three.

Triunfo, Baja California, May 26.

John A. Reid.

Cyanidation of Ore Containing Both Coarse and Fine Gold.

The Editor:

SIR—W. A. Caldwell, in his letter on 'Cyanidation of Ore Containing Both Coarse and Fine Gold,' published in your issue of May 30, quotes from an old article by C. H. Aaron (which, by the way, I have never seen) in which the latter advises miners having trouble with their plates to place bars of iron on them, with the idea probably of forming a galvanic couple, thus making the plate more active as an amalgamator. On trying this combination, and using ordinary water as the electrolyte, I find that there is a feeble current of about 0.04 volt flowing in the solution from the iron to the amalgamated plate. Should the water contain any free acid, or soluble acid sulphate, a stronger current would, of course, be produced.

Later on he advises the use of a dilute solution of KCN in the mortar, apparently forgetting that this will reverse the direction of the current in his couple, and give a comparatively strong one (0.4 volt) from the plate to the iron, thus dissolving the plate instead of protecting it. It may be that it was not intended to use the iron bars in this case, but even so there would, of course, be some solvent action on the plate. His suggestion of using zinc or cadmium amalgam is simply a substitution of these metals for the sodium in sodium amalgam, the use of the latter in amalgamation being, I believe, first proposed by Sir W. Crookes. The zinc or cadmium would be less costly than the sodium, but would probably be less effective. The method proposed in my letter of January 18, using zinc strips, would result in forming a certain amount of zinc amalgam, and perhaps would help the amalgamation to some extent.

There is a slight typographical error in my former letter as printed. On the third line from the bottom of the page, the line, "The couple \( \text{Zn} \rightarrow \text{CuHg} \) (amalgamated plate)," should be: The couple \( \text{Zn} \rightarrow \text{CuHg} \) (amalgamated plate). The arrow separating the electrodes and showing the direction of the current was also omitted.

New York, June 25.

Jas. S. C. Wells.

GOLDFIELD, NEVADA.—VII.

Written for the MINING AND SCIENTIFIC PRESS
BY T. A. HICKELD.

Goldfield has squandered its gold. The proportion of profit that has reached the owners of the mines has been pitifully small. Thus, the Florence has probably yielded $4,000,000 worth of ore, and yet the shareholders have received only $210,000 in dividends, that is, about 5%. There is $350,000 in the treasury. Of course, the lessees have made fortunes, the miners have stolen fully half a million dollars, and the remainder has gone to the smelters and railroads. But a net profit of 5% on ore averaging over $200 per ton is a miserable result from an economic standpoint. The big group of the Goldfield Consolidated produced fully $6,250,000 gross in 1907, and out of this the shareholders have had two 10-cent dividends, making $710,000, although the profits to the company were $1,760,358. The lessees made about $2,000,000 and the miners stole fully $1,000,000—figures that made the dividends look small enough. The Consolidated group has produced $16,500,000 to date, in 4½ years. Mention may also be made of the Tonopah mine, which has produced fully $17,500,000, and yet the total dividends to date aggregate only $3,450,000, about one-third of which was derived from the Tonopah-Goldfield railroad. Of course, a 100-stamp mill has been built at a cost of $900,000, and a power plant for $250,000, and a branch railroad, and improvements of many kinds; nevertheless it is astonishing to note how little benefit the shareholders have derived from this bonanza. If we add the production of the three mines (the Florence, Goldfield Con., and Tonopah) since their incorporation, we get a total gross yield (not including ore stolen) of fully $38,000,000, out of which lordly sum only a driblet of $4,370,000 has reached the shareholders. It is disgraceful, and constitutes a striking contrast with Cobalt, another boom camp where men went wild, where transportation facilities were no better than in Nevada, and where even the Government hindered rather than facilitated development. Added to these difficulties were those of a hostile climate, the long semi-arctic winters impeding the efficiency of labor far more than the burning summer heat in the dry air of the desert. The ore has yielded massive native silver, easy to steal. No effort has been made to treat the output from the mines by local reduction works until recently, so that the railroads and smelters enjoyed full opportunity to reap an excessive harvest. Yet from a total production of $6,000,000 per annum for four years it is estimated that over 60 per cent has come into the mine-owners’ pockets as profit. In 1907 the Nipissing mine yielded a gross return of $1,245,819, from which a net profit of $923,788 was realized, a result that is without parallel among the phenomenal gold mines of the Nevada camps. Indeed, the record of waste and loss was less startling at Guanajuato and Pachuca in the old bonanza days of the eighteenth century than at Goldfield and Tonopah in the twentieth.

Where did so much money go? As already indi-

cated, many lessees made fortunes while operating under royalties ranging usually from 20 to 25% on the smelter returns; much ore was stolen and divided among the criminal class; a large fraction went to the railroads and smelters under cover of rates that were, in effect legalized robbery.

Until September 1907 the smelters charged:

An ounce of gold is worth $20.67, so the deduction when paying $19 per ounce on a 5-oz. ore is not less than $0.35 per ton, that is, the real smelting charge is double that stated. The cost of smelting on a neutral basis is about $4 per ton. As the smelting rates were delayed until the Goldfield ore was sent are at Selby (near San Francisco) and Garfield (near Salt Lake), the distance it was transported ranged from 500 to 750 miles. The same rates were charged to both points. They were scaled according to the assay-value of the ore, thus:

<table>
<thead>

</tbody>
</table>

The freight-rate is adjusted on the basis of the sampling at the smelter. Above $300 the railroad charged $20.90 per ton, plus 4% on all valuations above $300. Thus on $500 ore, the rate was 4% of 200 or 8$ plus $20.90, making the total charge for transport not less than $28.90, that is, an ounce and a half of gold at the smelter valuation of that metal. The 4% extra was made up from two charges of 2%, the branch road to Mina levying an extra toll of 2% on ore above $300 valuation, while the main road from Mina to the smelter levied 2% more. This double charge ceased when the two railroad systems were consolidated, so that the extra rate is now 2% only—but that is enough.

In October the money market was disorganized. The smelters were unable to carry large supplies of ore, they became over-stocked, and levied rates that were frankly prohibitory. It is fair to add that owing to the congestion of traffic on the railroads, the smelting companies were hindered in getting cash, for the bullion was so delayed in transmission that realization on ore purchased from the mines was postponed an extra 30 days. The freight and smelter rates became:

<table>
<thead>
<tr>

<tr>
<td>75 to 100</td>
<td>37.00</td>
</tr>
</tbody>
</table>

Besides, of course, the indirect deduction made
by paying less than the mint price of gold. Thus on $100 ore, the total exaction became $45.35. It reminds one of the early days—50 years ago—when smelting was beginning and everything was carried across the plains in ox-wagons. In the days when it was necessary to encourage better transportation, the payment of bonuses for such a service was well enough, but now the railroads take no extraordinary risks and are entitled to no extraordinary tribute.

On December 12 the freight rates were reduced, thus:

<table>
<thead>
<tr>
<th>Assay</th>
<th>Per ton.</th>

</tr>
</tbody>
</table>

The addition of 2% on any excess valuation above $300 remained as heretofore. It will be noted that the improvement in rates is on the lower-grade ore. And it is to be remarked that this arbitrary charge of an extra 2% on ore worth more than $300 is not accompanied by any liability on the part of the railroad company, which refuses to hold itself liable for a valuation in excess of $100 per ton, unless compelled by means of litigation. Even if the shipper is willing to release the railroad company from any extraordinary liability on excessively rich ore, this arbitrary charge of an extra 2% is made. It is the unblushing application of the principle of charging "all that the traffic will bear."

On February 6, 1908, the smelter rates were reduced, thus:

<table>
<thead>

When the gold in the ore is in excess of 5 oz. per ton, an extra charge of 50 cents per ton for each additional ounce is made, so that on 7½ oz. ore, the extra charge is $2.50, making the total direct charge for smelting $12.50, to which the deduction from the mint value of gold must be added, namely $8.77, making the total exaction not less than $21.27 per ton.

To these smelter and railroad charges must be added the cost of sampling, which is $1.50 to $2 per ton, according to tonnage. Last year it was $2 to $3 per ton. The Western Ore Purchasing Co. and the Nevada Goldfield Reduction Co. have sampling works and receive ore, both as buyers and as brokers for the smelters.

It is no wonder that metallurgical ingenuity has been busily occupied in trying to find a cheap method of treating the ore on the spot, so as to escape these impositions from the railroads and smelters. The real benefactor of Goldfield and Tonopah has been the metallurgist who has devised an effective method of applying the cyanide process to the ores of these districts. I do not say that the railroad did not help to stimulate development or that the smelter did not help in marketing the ore, but of both it is fair to say that they have "the fault of the Dutch, of giving too little and asking too much."

Now that mills have been built and others are in process of rapid erection, the smelting and railroad rates will tumble. At Millers, a junction point on the railroad 42 miles from Goldfield and 31 miles from Tonopah, there are two large mills which treat the ores of the Tonopah and Belmont mines. The Montana-Tonopah has its own mill at Tonopah. At Goldfield, the Consolidated Co. will have the Combination mill and its new 100-stamp mill, to be completed by November. Besides these are the custom plants of the Nevada Goldfield Reduction Co. and the Goldfield CI Mill Co. Escape from the grasping hands of the railroad and smelter is assured.

With this prospect of competition, the railroad is likely to reduce its maximum rate to $12, keeping the minimum at $6, for the only ore to be sent out of the district will be the rich stuff. Smelter rates are likely to become $6 on ore under $50 and $8 on ore up to $100. It is likely that the $10 charge on ore assaying $100, and over, will be maintained, but the penalty of 2% on ore carrying more than 5 oz. gold is likely to be abolished. This is necessary if the smelting companies are to get the high-grade ore in competition with the mills. On ore above $300, the old penalty is likely to be maintained because the mills are not eager to treat this extra-rich ore. Such rules and exactions are what provoke men to wish for a benevolent despot or an interfering paternalism, to curb the frankly predatory instincts of corporate agencies. The smelting and the railroad corporations will come to an agreement as to how much each is to have. Just now the smelters are trying to get the railroad to reduce its tariff. When an adjustment has been made, it is probable that $50 ore (2½ oz. gold) will be the dividing line; ore richer than that going to the smelters, ore less than $50 going to the mills, and as the mines grow in size, milling methods improve, and competition between the mills develop, there will be a tendency to treat an increasing proportion of the output in Goldfield itself.

Some idea of the rate of production to be made from the Goldfield Consolidated mines is obtainable from the fact that the new mill will treat 600 tons per day, in addition to the 80 tons now treated in the Combination mill. This output of 680 tons will average $30; with a recovery of 90%, this means $18,000 per day or about $5,500,000 per annum. In addition there will be 30 to 50 tons of ore daily, averaging $80 to $300 per ton, sent to the smelters. It will be economical to mix the high-grade stuff with that which will yield a small profit, for in milling as in smelting it is possible to improve results by suitable mixture of ores. Thus, by adding
a small quantity of very rich ore to the daily feed in the Combination mill, good results are obtained. Recently the old Reilly lease-workings were tapped on the 280-ft. level of the Combination and a streak was found there 15 inches wide assaying 40 oz. gold. By distributing a ton of this stuff over 24 hours of mill-feed, the tailing was not enriched unduly and yet a good extraction was obtained by amalgamation, while the value of the concentrate was increased. In this manner the company is enabled to ship concentrates only and avoid the extortionate charges of smelters and railroads. Mining costs are from $3 to $4.50 at the Combination. In the Consolidated group the average cost of mining, development, and general expenses should not exceed $4 per ton. Transport to the mill will cost 10 cents. The average milling cost is now $6.50; in the big mill it should be not more than $2.25 per ton. Thus the total operating cost should be under $6.50. This is doing well. Kalgoorlie got down to such low costs after 10 years, Goldfield will have done it in two, by reason of the benefit derived from the experience of other gold mining districts. Let us hope that the period of squandering, of gutting mines to enrich ore-thieves, gambling saloons, bunco-brokers, railroads, and smelters is past, and that the profit will go first to the shareholders, the owners of the mines, and then, but not until then, to all the others who are the indirect beneficiaries of successful mining operations.

While the prolific production of gold has given point to the name of this Nevanian mining district, there is one feature of even greater interest to the engineer, namely, the conquering of natural obstacles. The creation of a hive of industry in a desert, by the construction of railways, the building of lines of power-transmission, and the bringing of water from a long distance—this is a fact to which every intelligent visitor must bow respectfully. It is part of the conquest of man over nature, the winning of the abomination of desolation where the sagebrush lifts an ashen face to an azure sky and barely hides the alkaline waste that was not ready for the habitation of man.

The electricity used for power and illumination at Goldfield comes from energy generated at the head of Bishop creek, in the mountains of the Sierra Nevada. The power-plant is in California, 95 miles west of Goldfield. The power is derived from the water issuing from a number of lakes, the highest of which is 9630 ft. above sea-level. There will be five power-houses eventually; at present three are built. Two of these (No. 4 and 5) generate 7500 kw., equivalent to 12,000 hp. During the present year the third plant will be completed, adding 8500 kw., or a total of 16,000 kw. One horse-power is equal to 746 watts. Both Pelton and Doble wheels are employed, the water being utilized five times over.

The original transmission-line was made of aluminium wire, No. 0, B. & S., equivalent to 0.32486 inch. The second, or parallel lines, is made of copper, No. 00 wire, equivalent to 0.3648 inch. Mr. Delos A. Chappell, the president of the company (named the California & Nevada Power Co.), informed me that they were forced to take copper for their second line because of their inability to get aluminum promptly. The voltage is 55,000. The wires are strong so as to give the proper sag under varying temperature, so that the maximum stress equals one-quarter of the ultimate strength. Allowance is made for a minimum temperature of —20° F. The cost of power to the consumer ranges from $6.50 to $15 per hp.-month, as measured on the low voltage side of the consumer’s static transformer by Westinghouse polyphase integrating watt-meters installed by the power company. This applies to large contracts; in small ones the measurement is by peak-load, taking 90% of the record.

The water supply of the town comes from the Goldfield Consolidated Water Co., which owns springs on Magruder Mtn., near Lida, 30 miles distant. A pipe-line was built in 1907, the water being delivered on October 4, 1907. The first pipe-line was defective, but the manufacturers made good, substituting new pipe. The actual cost of water is $1 per 1000 gal. when used in the mills of the district. This may be compared with the cost of water in Western Australia, where the Government built a reservoir and pipe-line 353 miles long, at a cost of $15,700,000, and delivers water at a maximum cost of $2.40 per 1000 gallons.

A brief description of the district as it appeared from a central elevation may prove of interest to those who have not been to Goldfield and it may prompt a contrast in years to come. Standing just outside the shaft-house of the Little Florence lease on one of the many hillocks rising above the desert, the view (on April 11, 1908) was as follows: To the west on a flat plain is the town of Goldfield, with a population of about 15,000. The multitudinous small dwellings, like matchboxes of varied color, are dominated by several large structures of brick and stone, among which are conspicuous the Court House, the new hotel, the School, the News building, the Casey hotel, and the Hippodrome. The last is not the Stock Exchange, as might be supposed, but a place for prize-fights and other diversions. Over-looking the town farther to the west is the edge of a ‘malapai’ (Spanish ‘mal’, bad, and ‘pais’, land)
terrace, a mesa capped by basalt and underlying tuffs. In the distance is the snow-covered crest of Montezuma mountain.

Southward the malapai swings across the horizon and is broken by low hills, surmounted by remnants of lava. In the middle distance are several shafts and head-frames: the Combination Extension, White Rock, and Portland. At the foot of the hill on which the observer stands is the Florence Extension.

Turning eastward the sky is cut by a red hill, of that name. The dumps and head-frames in the intervening flat, mark leases on Consolidated ground. Due east, there is a break in the ridge forming a pass through which the Clark railroad goes to Los Angeles and also the Broek railroad to Rhyolite. The nearer of the two tracks (which connects Tonopah to Rhyolite) appears to follow the wagon-road and has a steep gradient, over 4%. Beyond the railroads are a number of broken ridges with combs of silicified rhyolite. A sprinkling of dumps and head-frames indicates the position of the C. O. D., Kansas City, Atlanta, Gold Bar, and Cimarron mines.

Swinging northward, just across the nearer line of railroad, rises a large mass of black rock, the mineral possibilities of which are now being tested in the B. Fraction. Then the view includes a large number of mines just east of the main ore-channel; among these are the Jumbo, Cleremont, and Velvet. In the immediate foreground is the new Florence mill and nearly half a mile northwest the Combination mill; beyond the last is the Western Ore Purchasing Co.'s sampler and the works of the Nevada Goldfield Reduction Co., and the Goldfield CI Mill. All these metallurgical establishments are in the flat north of the town and punctuate the picture assertively.

Almost due north are the Consolidated mines, with the Mohawk shaft-house and those of the Red Top and Laguna. In the same direction farther away is the Kinkhead mill and the Booth mine near the base of Columbia Mtn., a conical hill rising about 1000 ft. above the flat and dominating the view northward. On the west side of the mountain can be seen the grade of the new railroad to the Consolidated Co.'s new mill, now under construction, and below it is the old (that is oldest, for 5 years means 'old' in Nevada nowadays) town of Columbia.

Looking northwestward over the flat to the left of Columbia Mtn., is a wide desert plain of alkali and sagebrush and in the distance rises the mass of Lone Mtn. To the right of Columbia Mtn. and on the northeast horizon are the white peaks of the Toiyabe range and north of them is Jefferson peak of the Toiyabe range. Over the northerly edge of the base of Columbia Mtn. runs the yellow line of the automobile road to Tonopah, the site of which is indicated by the Butler Buttes just east of a yellow hill named Gold Mtn. Between the Tonopah hills and Goldfield the desert stretches, a dreary waste, threaded by the road connecting the two mining districts, which are linked by a sequence of discovery and by the human history that has changed the waterless wilderness into a hive of industry. Overhead is a flawless sky, the vast expanse of hill and plain is bathed in brilliant sunlight and vibrant in an air as pure as the morning of Time.

Zinc-smelting in a blast-furnace has been commercially used in Sweden for some time. The blast is suppressed, and the requisite heat is obtained by the aid of an electric current instead of fuel. The furnace greatly resembles a cupola furnace for producing copper matte. It is mechanically charged at the mouth, and provided with a water-jacket. The rheophores are placed in the same position as the tuyeres of a blast-furnace. The liquid zinc is collected in a crucible, and a slag is formed, which, as in blast-furnaces, is tapped discontinuously. Such furnaces, producing 5500 tons of zinc yearly, have already been working for a few months at Leadville, Colo.; Valerdelia and Santa Barbara, Mexico. Construction and working of furnaces capable of producing 56,000 tons yearly is said to be feasible.—Revue Scientifique.

Colored wood is the subject of a recent patent by a Norwegian firm. Whole trunks of green trees are colored, the sap being pressed out and the dye injected in its place. It is claimed that wood treated by this process is more durable than ordinary wood, and that it will not warp.
THEORY OF THE SETTLEMENT OF SLIME.

Written for the Mining and Scientific Press
By H. S. Nichols.

Critical consideration of the factors affecting the settlement of slimes, is necessary to an appreciation of the relative degree of their importance. Taking the effect of an increase of temperature first, it has been suggested that the acceleration in settlement thus produced might be due to a corresponding decrease in the specific gravity. In this connection, however, pulp must not be confounded with liquid medium; for instance, it might be assumed that a corresponding effect would be produced by reducing the specific gravity of the pulp by the addition of water. The relative rates of settlement of a fine clay slime in pulps of varying density were found to be as represented by the plotted curves, Fig. 1. The specific gravity of a thin pulp may be reduced by an amount approximately 0.006 by raising the temperature from 60 to 100°F. This difference in specific gravity may also be brought about by reducing the solids in the pulp by 1%, or in other words, by adding water to a given pulp, and it will be seen that the thinner the pulp, the greater the amount of water to be so added.

The amount of water to be added might be calculated roughly from the formula: \[ N = Y (99.4 + N) - X \]
where \( N \) the number of units of water to be added,
\( Y \) the specific gravity of the pulp at 100°F,
\( X \) the weight of 100 units of pulp at 100°F.
The effect on the specific gravity produced by diffusion is not to be compared with that produced by increase of temperature as affecting settlement, however, for the solid particles of a pulp cannot be considered as passing through the pulp beneath them.

Temperature and electrostatic conditions both are factors affecting the falling of solid particles in liquids, and both are to be considered in relation to the principle of free settlement. It may even be allowed that in the electrostatic condition is to be found the force which retards settlement, and it is clear that when particles are free to fall, the specific gravity of the liquid medium is of importance and the greater the accumulation of solid particles, the greater will be the operation of the electrostatic force, and the more will the effect of temperature be discounted. Before leaving this question of temperature, it was also considered in connection with the effect of occluded air. The settlement of solid particles may very well be retarded by clinging air blebs. Heating and agitation undoubtedly dissociate the occluded air. A series of tests was made, the results of which are plotted in Fig. 2. For the purpose of these and all following tests, a very fine clay slime was used, containing no free silica. This clay was taken by the courtesy of Mr. S. S. Fowler from a decomposed dike found in the Blue Bell mine in the West Kootenay district of British Columbia, and was practically clean silicate of aluminum.

A stoppered graduate was filled with pulp made from this slime, containing 2.33% solids, and allowed to settle at 60°F, care being taken to maintain a uniform temperature. The pulp was then raised in temperature to 100°F, and agitated so as to remove as much air as possible, the graduate being full, and the rate of settlement was again noted. The same steps were taken at 140 and at 190°F. The pulp was then allowed to cool down to 140, 100, and 60°F, and the settlement noted in each case. The plotted curves show the rate of settlement and it will be seen that in the descending series the results obtained were practically the same as in the ascending series. Thus the theory of occluded air affecting settlement to any marked extent was abandoned. Next the effect of the addition of different electrolytes was tested, with the results as plotted in Fig. 3, and sulphuric acid was adopted as being the most effective. Fig. 4 shows the plotted results obtained with pulps of varying density, first at 60°F, second at 100°F, and third, with the addition of 4% of sulphuric acid at 60°F. For these tests the clay slime was slightly roasted, as more definite readings were thus rendered possible. Fig. 5 and 6 show curves plotted from Fig.
4. showing the settlement in millimetre during 30 minutes and 60 minutes, respectively.

From the results shown in the several plotted curves, the following conclusions are deduced:
1. In thin pulps, temperature may be more potent than electrolytes.
2. In thicker pulps, the addition of electrolytes may be double the added rate of settlement produced by increase of temperature.
3. As pulps settle, the effect of the addition of electrolytes bears a more constant ratio to the state of density (see Fig. 6, curve 3).
4. In pulps containing higher than 15% of solid matter, the effect of both the addition of electrolytes and the increase of temperature becomes rapidly obscured.

These deductions are explained as follows:
1. In thin pulps, repulsion of particles and counteraction of gravity, due to the electrostatic condition, are reduced by diffusion, the particles being farther removed from one another, and therefore any cause affecting the relative densities of the solid and liquid constituents of the pulp would produce more marked effect than that affecting the electrostatic condition.
2. In thicker pulps any cause counteracting the repulsion due to the electrostatic condition would be more and more potent as the particles are crowded in closer proximity to one another.
3. The effect of the addition of electrolytes, being thus in relation to proximity of particles, would be more steadily affected as the pulp increases in density, and free-falling is interfered with, than would that of reduction of the specific gravity of the liquid medium.
4. The economic use of electrolytes is limited, and it may therefore be assumed that the addition of any electrolyte will produce an effect limited in degree, and as the repulsive force due to the electrostatic condition is rendered more operative by closer packing of the solid particles, such electrolyte will become inefficient and finally of no avail. This fact is further testified to as follows:
5. Increase of temperature always produces a more compact final settlement than addition of electrolytes, for in the final stage of packing, settlement is assisted, though very slowly, by the slightest variation in the densities of solid and liquid. The case may be diagrammatically represented as follows:

$$a \quad 0 \quad 0 \quad 0 \quad 0 \quad 0 \quad 0 \quad 5$$
$$b \quad 0 \quad 0 \quad 0 \quad 0 \quad 0 \quad 0 \quad 4$$
$$c \quad 0 \quad 0 \quad 0 \quad 0 \quad 0 \quad 0 \quad 3$$
$$d \quad 0 \quad 0 \quad 0 \quad 0 \quad 0 \quad 0 \quad 2$$
$$e \quad 0 \quad 0 \quad 0 \quad 0 \quad 0 \quad 0 \quad 1$$

With a given electrostatic charge or difference of potential, the force required to overcome repulsion...
and the initial or maximum velocity of the falling solid particles should be approximated to. Fig. 7
gives the plotted results obtained with a small model, a
modification of my apparatus for slime settling,
in which the settling chamber was made with straight
sides, into one of which a glass window was inserted.

The straight line indicating free settlement shows
that not only is the retardation, so clearly evidenced
in the other curves, entirely done away with, but the
velocity of falling of the solid particles was, even in
the case of the thickest pulp experimented with, simi-
lar to the initial velocity obtained with the thinnest
pulp.

Fig. 8 shows a comparison obtained with an addi-
tion of 2% sulphuric acid and with adoption of free
settlement in a pulp containing 2.56% of raw clay
slime.

Previous agitation, temperature, and diffusion, or
state of density make great difference in settlement
in the same material. With the fine clay slime used
in these tests, a pulp containing less than 1% of sol-
ids would not be clear for several days alone, but
with the addition of an electrolyte settled almost at
once. Again, a pulp of 2.5% solids, which settled as
shown (see Fig. 8, curve 1) under normal conditions,
after being heated to 200°F. and violently agitated,
showed no signs of settling after 48 hours.

DEFINITIONS OF IGNEOUS ROCKS.

The following brief definitions of the more com-
mon igneous rocks, all of which are encountered
throughout the desert region of the Southwest, will
be interesting and useful. The definitions are those
having the approval of the United States Geological
Survey, and are prepared to meet the needs of the
non-technical reader.

Alaskite is a granular rock of white or light-gray
color. It is composed almost entirely of quartz and
orthoelase. It is a granite lacking mica and horn-
blende.

Andesite is a porphyritic rock; that is, it has vis-
ible crystals (phenocrysts) embedded in a finer-
grained, often glassy groundmass. The most con-
spicuous features are the phenocrysts of hornblende
or biotite, or augite and plagioclase.

Aplite is the name applied to a finely granular
rock which usually occurs in dikes cutting, for ex-
ample, a granite. The aplite, which as a rule is more
silicious than the granite, in many instances has
solidified from a portion of the granite mass that
is still liquid at great depths.

Basalt is a black or dark-gray rock which is often
porous from the presence of steam-holes. Crystals
of olivine, plagioclase, and pyroxene may or may
not be visible in the dense or finely granular ground-
mass.

Dacite may be briefly defined as a quartz-bearing
andesite. The more basic dacites closely resemble
andesites, while silicious dacites are closely con-
ected by transition rocks to rhyolite and might be
confused with rhyolite were it not for the presence
of plagioclase crystals.

Diorite is a gray granular rock which is composed
essentially of plagioclase and hornblende, while biot-
ite or augite may also be present. Diorite and andes-
ite are similar chemically, but differ texturally.

Diorite porphyry is a rock of the composition of
diorite with abundant crystals of plagioclase, horn-
blende, and biotite. The groundmass is finely gran-
ular.

Granite is a granular rock of pink or gray color.
It is composed of orthoclase, quartz, and either mus-
covite, biotite, or hornblende.

Granite porphyry is a rock of porphyritic habit
having the same composition as granite. Quartz and
orthoclase are the more common phenocrysts, and
these are embedded in a finely granular groundmass.

Latite is a porphyritic rock with more or less
glassy groundmass. Phenocrysts of orthoclase and
plagioclase are present in equal amounts, while either
hornblende, augite, biotite, or olivine is usually also
present. Chemically, latite is the equivalent of mon-
zonite.

Monzonite is a granular rock resembling both
granite and diorite, but containing orthoclase and
plagioclase in approximately equal amounts. If
quartz is present, the rock is called a quartz mon-
zonite. It is usually of a gray color.

Monzonite porphyry bears the same relation to
monzonite as granite porphyry to granite.

Pegmatite is here applied to a coarsely crystalline
rock which occurs as dikes in some other rock—
granite, for example—with which it practically coin-
sides in composition. Such rocks are probably
formed by segregations from the original molten
mass of the enclosing igneous rock.

Rhyolite is a porphyritic rock with glassy base. It
has the same chemical composition as granite. The
most abundant phenocrysts are orthoclase and
quartz, although biotite, augite, and hornblende also
occur.

Syenite is a granular rock usually of gray color.
The component minerals are orthoclase and horn-
blende or mica. If quartz is present, the rock is
called a quartz syenite, and with increase in this con-
situent quartz syenite passes into granite. Where
the component minerals are rich in soda, the rock is
a soda syenite.

A high rate of progress was attained in the head-
ings of the Loetschberg tunnel, Switzerland, during
April, 1908. The advance of the south heading dur-
ing that month (28 working days) is within 5% of
the record established in the Simplon tunnel, when
685.5 ft. was driven in a single heading in one month.
The Loetschberg figures for April are 656 ft. for
the north heading and 521½ ft. for the south heading, a
total of 1178½ ft. The two headings have now pene-
trated, respectively, 6586 ft. and 5635 ft. into the
mountain, a total of 12,644 ft.—Engineering News.

Cresoting 'old-field' pine, the lobolly pine of the
Southern States, imparts to it a strength which is
equal to that of ordinary oak or hickory. Other infe-
rior woods are benefited in the same way, and the
range of relatively inexpensive mine-timbers is thus
greatly widened.
FLOOD DAMAGE AT THE GREAT FALLS
SMELTER, MONTANA.

Written for the MINING AND SCIENTIFIC PRESS
by F. S. Bixwell.

The Missouri and the Sun river valleys, in Montana were subjected to severe floods from unprecedented rainfall during the last week of May and the first week of June. The official observations show a precipitation of 5.3 in. on June 3, 4, and 5. Preceded by heavy snows in the Rocky Mountains, at the headwaters of the Missouri, and followed by a cloud-burst on June 5, the Missouri river at Great Falls rose nearly 5 ft. above its previous high-water mark. The water overflowed the race-walls at the power-house of the Boston & Montana Co.'s smelter, completely submerging them, and subjecting them to pressure-head of 3½ ft. above that for which they had been calculated. Owing to this fact, and to poor masonry construction, the north wall failed by sliding. On June 1, at 3 A.M., the power-house was developing 9635 hp. from 15 Victor turbines, ranging from 20 to 57 in. diam. This power was transmitted partly in the form of compressed air, partly by wire-rope drive, and partly as electric current. The accompanying view, looking down the railroad track, shows the east end of the power-plant, with the rope-drive and the air-mains, after the power-plant had been wrecked by the flood. The view of the river and walls shows at D where the north wall failed, causing the destruction of the power-plant. At E the south wall was dynamited to divert a part of the water back to the river. At C is a point where one of the three 17 by 23 ft. head-gates failed. The letter A refers to the north approach of the suspension bridge, and B to the centre pier of the suspension bridge, destroyed at 9 A.M., June 8. In an effort to break the force of the current after the failure of the north head-race wall and the south gate, Superintendent Wheeler ordered four steel gondola cars, such as are used for hauling slime, to be dumped in of the power-house were completed January 6, 1901. The total cost of the dam was $175,000. The crest was 14 ft. above the sandstone ledge, giving an effective head of 40 ft. The minimum flow was 4000 cu. ft. per sec., and at 3360 cu. ft. per sec., 16,583 hp., or 12,287 net available horse-power. Of this, the Boston & Montana developed for their first unit 2600 hp., and for the electric light plant on the south side of the river 1100 hp. The total cost of power developed, including all charges and depreciation, was $49.19 per hp. per annum.

Actual operation has since shown that the maximum horse-power available at low water (December, January, and February) is less than 5000. Of this
quantity the smelter produces less than 3000, and the light and power plant produces less than 2000.

On June 19 the water was finally shut off, through the construction of a steel skeleton gate, designed by the company’s master mechanic, J. H. Klepinger. This gate was constructed of 12-in. lightest section I-beams and channels, with an average spacing of 16 in., and a 17-ft. span. The idea in constructing a skeleton gate was to offer the least possible resistance to the water pressure while sinking. The gate dropped 11 out of the 23 ft. by its own weight. 4 more by weighting, and the balance by jacking. Finally 4-in. sheet-piling was driven parallel to the gate on the up-stream side, which effectually stopped the flow and the farther destruction of the plant.

To properly re-construct the gates, gate-house, head-race, penstock, and power-plant will cost close to $500,000. At the time of the shut-down the plant was producing 120 tons of copper and 2100 lb. silver per day. The company’s cost-sheets show a total production cost of 10.1c. per lb. for copper. Depending upon the price of copper and silver for the coming three months, the total gross loss to the Amalgamated Co. will apparently foot up to about five million dollars.

**A CAUSE OF MISLEADING AIR ANALYSIS.**

On a warm day with the laboratory temperature at 72°F., and the vapor pressure of water as high as 20 mm. of mercury, a serious error may result in the readings of gas-volumetric apparatus. Vapor pressure of 20 mm. says James Moir in a communication to the Chemical & Metallurgical Society of South Africa corresponds at this altitude (about 4000 ft.) to 3.23% of water-vapor in the air; consequently in analyzing air over water the oxygen percentage of the dry air is apparently depressed by 0.7%; while the difference (reported as nitrogen) is affected by two errors, namely, the above 0.7% and in addition the actual quantity of water-vapor present. Thus a sample of air containing when dried 20.95% oxygen, 0.05% CO₂, and 79.0% nitrogen when introduced into an Orsat at 72°F., will expand by 3.3%; and the analysis will give CO₂ = 0.05%, O₂ = 20.25%, residue = 79.7%. Seeing such an analysis, one would suppose that some of the oxygen had been used up, but in fact the apparent deficit is due entirely to dilution with water-vapor. Again, 3.2% of the residue is water-vapor, so that the true value of the inert gases (mainly nitrogen) in the saturated sample is 76.5%; the depression from 79.0% corresponding exactly with the dilution of the dry gas with 3.3% of water-vapor. Consequently, to get comparable results with such apparatus, it is necessary to recalculate the observed readings. It would be more correct theoretically to use in the calculation the actual percentage of water-vapor present at the time of sampling; but in practice it is usual to calculate back to dry air, so as to be able to compare directly with the existing standard analyses of fresh air. Thus if the observed readings are: CO₂ = 0.1, O₂ = 20.2, residue = 79.7, and the temperature of the water is 70°F., the barometer reading 620 mm., that is, vapor pressure = 18.6 mm., then percentage of water-vapor is \( \frac{18.6}{760} \times 100 = 3.0\% \). Consequently 100 c.c. of the wet gas contains CO₂ = 0.1 c.c., O₂ = 20.2 c.c., N₂, etc. = 76.7 c.c., H₂O = 30 c.c.; which quantities are also contained in 97 c.c. of the dry gas; therefore the true analysis of the dry gas is (multiplying the figure by \( \frac{100}{97} \)), CO₂ = 0.103%, O₂ = 20.825%, and N₂, etc. = 79.072 per cent.

An example of such a fallacy is the deficiency of oxygen always observed in mine air. The atmosphere in mines is usually near saturation, and consequently dry air entering the downcast with, let us say, 21% oxygen, will through mere dilution with water-vapor contain only about 20.5% by the time it reaches the foot of the shaft. In spite of this elementary fact, many scientists have attributed the fall in oxygen to such things as the oxidation of pyrite or timber. It should also be noted that the state of humidity of the air also affects the results of CO₂ determinations by Pettenkofer’s method, but only to a slight extent. The observed barometric pressure should be diminished by the existing vapor tension at the time of sampling.

**MORTAR.**

When quick-lime is being slaked it must be kept wet. In addition to wetting it by addition of water from a hose, it is proper to have standing a barrel full of water, so that this can be dashed by the pailful upon the lime as it is crumbling. Lime loses strength if allowed to “burn”. Though the practice is frequently disregarded, the making of lime-mortar should begin two or three weeks before it is used. It is more expensive to do this than to make the mortar and to use it as made. To make up mortar and have it standing causes extra handling and greater labor in “tempering”, so that the temptation is to adopt the other and easier way. Lime-mortar must be tempered until all the white spots or specks disappear, otherwise the spots, which are the unslaked part of the lime, will eventually swell and break the initial set of the mortar after the bricks are laid. Hence the necessity for curing it the length of time above specified. When it is proposed to make cement-lime-mortar, do not add the cement to the slaking lime-mortar. Cement must be thoroughly mixed dry with sand before it is added to the already-made lime-mortar, and this addition is to be made just before the mortar is used. Cement-lime-mortar when setting forms microscopic inter-locking crystals, and these crystals if broken, will never properly re-unite. If then the mortar be allowed to stand a while and is then used, this initial set is broken and the mortar is permanently weakened. Granting that the mortar has been properly laid, there is a further chance of damage if the work is allowed to dry out rapidly, and numerous instances could be cited of unsatisfactory work from this cause. When putting in concrete, thoroughly wet the forms in which it is moulded, or else grease them so that they will not soak up water from the concrete. Also wet the ground thoroughly before laying concrete, and after putting it in do not allow even a dry plank to lie upon it for at least two days after work is finished.
COPPER SMELTING IN SIBERIA.

Written for the MINING AND SCIENTIFIC PRESS
By WILLIAM A. REYNOCK.

Copper smelting at the Spansk works, in the Akmolinsk district of Siberia, has been carried on for forty years. Two of the features of the Russian operations are remarkable, namely, smelting in brick blast-furnaces with soft coal fuel and the production of a slag very low in iron. The ore smelted is hauled 72 miles by canoes or oxen to the smelter. Twenty-six miles in the other direction the company owns large coal mines of a fair quality of soft coal containing about 12% ash. The smelter is 560 miles from the nearest station on the Siberian railway. These long hauls are made at an astonishingly cheap freight, less than some of the railway rates in South Africa. Machinery has hauled the 560 miles for about $15 per ton. Ores are hauled the 72 miles from mine to smelter for about $3 per ton.

The following is a typical analysis of the ore:

<table>
<thead>
<tr>
<th>Element</th>
<th>Weight %</th>
</tr>
</thead>
<tbody>
<tr>
<td>Fe</td>
<td>2.9</td>
</tr>
<tr>
<td>Al₂O₃</td>
<td>2.7</td>
</tr>
<tr>
<td>CaO</td>
<td>0.4</td>
</tr>
<tr>
<td>S</td>
<td>6.8</td>
</tr>
<tr>
<td>BaSO₄</td>
<td>27.3</td>
</tr>
<tr>
<td>SiO₂</td>
<td>40.3</td>
</tr>
<tr>
<td>Cu</td>
<td>16.4</td>
</tr>
</tbody>
</table>

More than an equal weight of limestone containing 51% CaO is added for flux and about a third of the charge consists of old rich slags. The ore is smelted in brick blast-furnaces 4 by 20 ft. at the tuyeres and in smaller ones 4 by 10 ft. The height from tuyeres to charge-floor is 5 ft. About 35% of soft coal is used. The furnaces run very slowly, producing matte containing 55% copper, some black copper, and at the same time very often a quantity of cast iron runs out with the matte.

The following is an average analysis of the slag during one month:

<table>
<thead>
<tr>
<th>Element</th>
<th>Weight %</th>
</tr>
</thead>
<tbody>
<tr>
<td>SiO₂</td>
<td>45.5</td>
</tr>
<tr>

<td>33.1</td>
</tr>
<tr>
<td>BaO</td>
<td>6.6</td>
</tr>
<tr>
<td>Al₂O₃</td>
<td>8.2</td>
</tr>
<tr>
<td>Cu</td>
<td>0.18</td>
</tr>
</tbody>
</table>

I have never seen any record of a slag containing such a low percentage of iron produced in copper smelting. It is also remarkably clean, considering that rich matte and black copper were made; but this is due to the low specific gravity and slow running. Attempts were made to make a more fusible slag by adding an iron ore containing 68.6% Fe₂O₃, but the reducing action of the furnace is so strong that instead of going into the slag it was converted into east iron. Movably fore-hearths were used; usually in one day they would become filled with copper and chilled slag and matte. Experiments were made with reverberatory furnaces and it was found that iron could be used for a flux and a better slag made.

The matte and black copper are treated in a small reverberatory furnace having circular hearths 7 ft. in diameter. The hearth and arch are both formed by beating ground quartz and clay in place over wooden forms. When the matte is melted, a current of air is blown on the surface until copper is produced. Black copper is refined in a similar furnace, producing refined copper of fair grade.

STEADY-PAY MEN.

For the purpose of retaining and having available good mechanics and other men in construction work, the 'Field system' makes provision for keeping them busy when the weather or other causes prevent carrying forward the work. The rules applying are:

1. All steady-pay men are to arrive on the job before the first whistle has sounded, and must remain there until quitting time, regardless of the weather. They must not hang around doing no work, but must be actually engaged upon needed work.

2. Foremen and time-keepers are to report to the engineer in charge, before starting and before quitting work.

3. Apprentices are subject to all the rules of steady-pay men. They are to be kept busy, and instructed in their work.

4. When work is stopped, owing to bad weather, if there is no other job for them, steady-pay men may do work upon jobs, which it may be useful to enumerate as suggestions to others, namely: Making trestles and horses for scaffolds, repairing wheelbarrows, repairing hoes, mending hose, repairing engine-horse or other buildings and lockers, putting handles on tampers, cleaning up tool-house, cleaning transits, preparing staging and runs, sharpening saws and tools, sawing handles off worthless shovels, checking up lines and levels, checking dimensions as of steel and iron, pipe, door and window frames, dimension-stone, and the like, brushing off or cleaning roofs, sills, or projections, so that rubbish will not be washed by the rain into the conductor-pipes, cleaning the sills and projections so that the mortar will not take stains from the rain, cutting stone for arches, cutting brick, branding and stamping tools, stacking lime and cement in a dry place 6 in. clear from the ground, and in such order that the oldest will come out first, packing cement bags for return, making needed tool-boxes for storing small tools, and so forth.

Every superintendent, engineer, and the men themselves, must suppress subscriptions for presents, and other forms of graft. All steady-pay employees, whether working or not, even in vacation, should keep the office notified of their addresses. Foremen are required to work in harmony with one another, and all steady-pay men get credit or blame according as the job is well or poorly conducted. The steady-pay men are working in the interest of the firm; therefore, their private character, and their conduct outside of working hours, is counted in considering promotions.

Windmills of the four-wing type having an area of 65 sq. ft. will in wind having a velocity of 13½ miles per hour (20 ft. per second) develop one horse-power.
**TUNNEL DRIVING AT LOW COST.**

Written for the *Mining and Scientific Press*  
By Walter H. Busch.

The driving of the Chipeta adit at Ouray, Colorado, was not especially notable as an important operation, but on account of the rapid driving and the resultant low costs, attention was attracted to it and considerable enquiry has been made as to the methods employed.

The adit was projected as a working entry to simplify the mining of the American-Nettie quartzite stratum, which had faulted downward. The portal is in the face of the steep mountain forming one wall of the canyon north of the town of Ouray, at an altitude of nearly 9000 ft. and 1700 ft. above the bed of the river. For economic reasons the power-plant was placed at the river and a line of 3% in. standard pipe laid on the surface to carry compressed air to the adit. This pipe-line, 3400 ft. long, has given no trouble in summer or winter.

During the installation of the plant and pipe-line, work was carried on by hand-labor, the adit reaching a length of 263 ft., including the portal section of 115 ft., which was heavily timbered 7 by 7 ft. in the clear. Machine-drilling was then started and a run, which lasted for five full months, was made, only two rounds of holes being lost in that period.

This run of five months (152 days) resulted in driving the heading 7½ by 7½ ft. in the clear, a distance of 1712½ ft. in hard rock; a monthly average of 342½ ft. The best weekly record was 85 ft.; the best month (31 days) was 359 ft. But two 8-hour shifts per day were employed. Economical considerations, not speed, being predominant always. Compressed air at about 100 lb. was supplied to a pair of 3½-in. New Ingersoll drills, both mounted on one single-screw column set horizontally above the muck-pile. The round, consisting of from 15 to 19 holes, was drilled—except the lifters—from this setting, the bar being re-set for the lifter after the muck was away. The 'cut' was taken from the bottom, uniformly. Three drill-men tended the two machines, drilling a full round each shift. An unusual system of 'mucking' was employed, which, perhaps more than any other one thing, may account for the substantial rate of progress that was reached and maintained. The tunnel track, 18-in. gauge, was carried close to one side of the adit, and a floor consisting of steel plates and planks was maintained with the greatest care for not less than 60 ft. back from the heading. This floor was moved forward every round. No switches or turnouts were used; cars measuring 20 cu. ft. capacity were specially designed and these, although weighing empty 1000 lb. apiece, were so perfectly balanced that the empty cars composing an incoming train were easily 'jumped' off the track onto this floor, the loaded cars passed by, and then the empties replaced on the track in detail as required by the muckers for loading. Muck was handled with No. 6 square-pointed shovels. Four shovellers and a mule-driver composed each shift. Track was laid and leveled by the muckers. Each shift, composed of drill-men and muckers, started work together. No ventilating system was installed, the smoke being blown back with air from the compressor. The adit throughout its entire length was perfectly dry.

This adit was an independent operation, the employees having no other occupation, so that their total wages are a charge against the work. Their wages were: Foreman, $5; drill-men and blacksmith, $4; blacksmith-helper, $3.50; muckers, $3; compressor-engineers, $3.50 per 8-hour shift. No bonuses were paid except on Christmas day, when double time was given. The following costs are computed from March 1, when 1835 ft. (including the portal section) had been completed, and embrace every item outside of construction and equipment accounts, which were closed before the current accounts were opened. The 'Power' account covers labor, coal, oil, and lights, everything at the compressor station: 'Labor' covers all other labor except that charged into 'Lumber and Timbers.' 'Tunnel Expense' covers tool-renewals and repairs, blacksmith's sundries, forgage, oils, and general sundries at tunnel; 'Track and Pipe' covers cost and transportation of rail, fittings, ties, pipe, and pipe fittings; 'Expense' covers city office, rent, furniture, and incidental expenses. The compensation of the acting superintendent is nowhere included in the costs as shown.

Pipe-line through tunnel is 3½-in. standard black pipe. Track is 16-lb. section, on ties laid 20 in. apart. Powder (40% dynamite) cost $0.1315 at the portal. Close estimation places its consumption at 14.5 lb. per foot for machine-driving. Steam coal cost $3 per ton at the boilers. The air-pressure was nominally 100 lb. and a recording gauge kept on the line proved of value in many ways. There was always plenty of air. No charge for depreciation of tools and equipment has yet been entered; renewals and repairs are made and charged currently to 'Tunnel Expense' and the actual value of the outfit to the company is about equivalent to new, as nothing has been allowed to run down.

The mines of the United Kingdom employed, during the year 1907, a total of 972,220 persons. Of these, 940,618 worked in the 3327 coal mines and 31,602 at the 748 metalliferous mines. The number of persons under 16 years of age employed underground in the coal mines was 6.9% of the total underground workers.

Traffic difficulties in Berlin have become so acute that the town council has voted $25,000 as a prize for the best plan of laying out future additions to the city with a view to distributing the traffic.
HUMAN SIDE OF A MINING ENGINEER'S WORK.

By EDMUND B. KIRBY.*

You have now reached the time when the care and sacrifices of your family are at an end, when faithful instructors have completed their labors, when the State has performed its duty. It is now in order for you to stand upon your own feet and to go your own way.

I would call your attention not to the technical, but to the human field before you. I do this because it is so often neglected by mining engineers, and because this neglect is apt to bring delay, disappointment, or failure. The special work of an engineer is to apply the discoveries and methods of science to the practical business of the world. Often he forgets how many-sided a man must be for this end, and absorbed in technical details he overlooks the fundamental requirements of life. I urge you therefore not to forget that the world is made up of things and of folks, and that nine-tenths of your business will be with folks. Science is a fascinating, but exacting goddess, and she brooks no rivals. She weaves a mystic spell about her devotees and normal human motives disappear. The love of gold, the dream of power, the hunger for social position, are forgotten. Scientists find themselves impelled by strange mysterious forces, unknown to the multitude, and by themselves but dimly understood. They pursue truth for truth's sake. They discover realities through the insatiable desire to know. Enthralled by the passion for exploration and discovery, they give profound intellectual effort, they expend lives of unsparking labor for a mere existence, often without the aid of recognition or of sympathy. Such men live apart and in a higher world. The enthusiasm kindled in the student's heart by the touch of the scientific spirit can never die out: It must always be the inspiration of the mining engineer. But his own life-work is sternly practical. It is the production of wealth from the forces and materials of nature. It leads out of the library and the laboratory into the busy world of men and affairs, and it calls for the well balanced man. This school has done what it could for your equipment. It has performed the duty for which it was created; it has awakened and developed your intellect; it has acquainted you with the methods and resources of science and of your profession. You represent the conscientious labor of earnest men who have brought you to a certain standard, of mental and technical equipment. But your social equipment has been left to chance. The only common training has been that derived from your student life together for four years. This has knocked off the corners and rubbed down the rough places, and is one of the advantages of a college career. So, as you stand today, varying in personal qualities, I call your attention to the fact that henceforth you are your own architects, and can re-construct as you please. To youth all things are possible, and you can, if you wish it, change these qualities in any way you like.

The business world is not interested in the details of your education. It is understood that by the completion of such a course the man has made good in his first test. This gives promise for the future, and the fact of technical training assures ease in breaking a new man into the business. You will find that a diploma is of little interest to others, but a likeable personality is a passport good for life and in all countries. In time you are to discover that taet and diplomacy solve more problems than engineering formulae. That a memory for names and faces will help you more than one for minerals and rocks. Sooner or later you will know that good sense, that ability to decide which of any two things is the more important, is an asset beyond price. You will awake to the fact that valuable as is skill in the higher mathematics, it will never push you to the front like the ability to write a letter which will really do its work. How will you deal with people if not through language, that means by which your thought and will may reach the consciousness of others, that delicate and subtle medium necessary for the simple affairs of daily life, yet capable under a master's touch of swaying a multitude, of moving the world? How far have you learned its use? You have studied the reactions of chemistry, but how much have you learned of those subtle human reactions which break down indifference and create friendship?

The technical side of a mining engineer's work is, and must remain, its distinctive feature. Next to the fundamental requirements of life, its importance is conceded by all. Not only is it necessary for him to shape his social qualities and general attainments upon broad-gauge lines, but it is well to recognize that the technical knowledge demanded by the mining world is broadening. The single specialist of former days is now under a disadvantage.

The mining engineer will always owe to his profession more than he can give, and the motives of obligation as well as those of policy, impel him to do all in his power for its welfare. This duty is the more imperative because it is a young profession, hardly more than a generation old. It has only of late been generally understood by the business world. During its growth, with advancing recognition, the professional spirit has steadily increased.

The American Institute of Mining Engineers was the first and the most powerful means of collecting and uniting a number of scattered specialists into a self-conscious profession. Its great and long continued work has been ably seconded by numerous other engineering societies throughout the world. But what is not so clearly recognized is the remarkable work of the mining journals in developing the professional spirit of engineers and the feeling of fraternity among them. Their prompt and thorough collection of news from the remotest mining districts, the eager search for scientific and technical knowledge, their interchange of views: these have been doing a constructive work for the mining world of which it is as yet but feebly conscious. Today

*Abstract of address before the graduating class of the School of Mines and Metallurgy, University of Missouri, Rolla, Mo., June 16, 1908.
TUNNEL DRIVING AT LOW COST.

Written for the Mining and Scientific Press
By Walter H. Bunc.

The driving of the Chipeta adit at Ouray, Colorado, was not especially notable as an important operation, but on account of the rapid driving and the resultant low costs, attention was attracted to it and considerable enquiry has been made as to the methods employed.

The adit was projected as a working entry to simplify the mining of the American-Nettie quartzite stratum, which had faulted downward. The old entries were tortuous inlines terminating at the fault. The portal is in the face of the steep mountain forming one wall of the canyon north of the town of Ouray, at an altitude of nearly 9000 ft. and 1700 ft. above the bed of the river. For economic reasons the power-plant was placed at the river and a line of 31/2 in. standard pipe laid on the surface to carry compressed air to the adit. This pipe-line, 3400 ft. long, has given no trouble in summer or winter.

During the installation of the plant and pipe-line work was carried on by hand-labor, the adit reaching a length of 263 ft., including the portal section of 115 ft., which was heavily timbered 7 by 7 ft. in the clear. Machine-drilling was then started and a run, which lasted for five full months, was made, only two rounds of holes being lost in that period.

This run of five months (152 days) resulted in driving the heading 71/2 by 71/2 ft. in the clear, a distance of 17121/2 ft. in hard rock; a monthly average of 3421/2 ft. The best weekly record was 85 ft.; the best month (31 days) was 359 ft. But two 8-hour shifts per day were employed, economical considerations, not speed, being predominant always. Compressed air at about 100 lb. was supplied to a pair of 31/2-in. New Ingersoll drills, both mounted on one single-screw column set horizontally above the muck-pile. The round, consisting of from 15 to 19 holes, was drilled—except the lifters—from this setting, the bar being re-set for the lifters after the muck was away. The ‘exit’ was taken from the bottom, uniformly. Three drill-men tended the two machines, drilling a full round each shift. An unusual system of ‘mucking’ was employed, which, perhaps more than any other one thing, may account for the substantial rate of progress that was reached and maintained. The tunnel track, 18-in. gauge, was carried close to one side of the adit, and a floor consisting of steel plates and planks was maintained with the greatest care for not less than 60 ft. back from the heading. This floor was moved forward every round. No switchers or turnouts were used; cars measuring 20 cu. ft. capacity were specially designed and these, although weighing empty 1000 lb. apiece, were so perfectly balanced that the empty cars composing an incoming train were easily ‘jumped’ off the track onto this floor, the loaded cars passed by, and then the capping replaced on the track in detail as required by the muckers for loading. Muck was handled with No. 6 square-pointed shovels. Four shovellers and a mule-driver composed each shift. Track was laid and leveled by the muckers. Each shift, composed of drill-men and muckers, started work together. No ventilating system was installed, the smoke being blown back with air from the compressor. The adit throughout its entire length was perfectly dry.

This adit was an independent operation, the employees having no other occupation, so that their total wages are a charge against the work. Their wages were: Foreman, $5; drill-men and blacksmith, $4; blacksmith-helper, $3.50; muckers, $3; compressor-engineers, $3.50 per 8-hour shift. No bonuses were paid except on Christmas day, when double time was given. The following costs are computed from March 1, when 1835 ft. (including the portal section) had been completed, and embrace every item outside of construction and equipment accounts, which were closed before the current accounts were opened. HUMAN SIDE OF A MINING ENGINEER’S WORK.

By EDMUND R. KIRBY.

*You have now reached the time when the care and sacrifices of your families are at an end, when faithful instructors have completed their labors, when the State has performed its duty. It is now in order for you to stand upon your own feet and to go your own way.

I would call your attention not to the technical, but to the human field before you. I do this because it is so often neglected by mining engineers, and because this neglect is apt to bring delay, disappointment, or failure. The special work of an engineer is to apply the discoveries and methods of science to the practical business of the world. Often he forgets how many-sided a man must be for this end, and absorbed in technical details he overlooks the fundamental requirements of life. I urge you therefore not to forget that the world is made up of things and of folks, and that nine-tenths of your business will be with folks. Science is a fascinating, but exacting goddess, and she brooks no rivals. She weaves a mystic spell about her devotees and normal human motives disappear. The love of gold, the dream of power, the hunger for social position, are forgotten. Scientists find themselves impelled by strange mysterious forces, unknown to the multitude, and by themselves but dimly understood. They pursue truth for truth’s sake. They discover realities through the insatiable desire to know. Enthralled by the passion for exploration and discovery, they give profound intellectual effort, they expend lives of unsparring labor for a mere existence, often without the aid of recognition or of sympathy. Such men live apart and in a higher world. The enthusiasm kindled in the student’s heart by the touch of the scientific spirit can never die out. It must always be the inspiration of the mining engineer. But his own life-work is sternly practical. It is the production of wealth from the forces and materials of nature. It leads out of the library and the laboratory into the busy world of men and affairs, and it calls for the well balanced man. This school has done what it could for your equipment. It has performed the duty for which it was created; it has awakened and developed your intellect; it has acquainted you with the methods and resources of science and of your profession. You represent the conscientious labor of earnest men who have brought you to a certain standard, of mental and technical equipment. But your social equipment has been left to chance. The only common training has been that derived from your student life together for four years. This has knocked off the corners and rubbed down the rough places, and is one of the advantages of a college career. So, as you stand today, varying in personal qualities, I call your attention to the fact that henceforth you are your own architects, and can re-construct as you please. To youth all things are possible, and you can, if you wish it, change these qualities in any way you like.

The business world is not interested in the details of your education. It is understood that by the completion of such a course the men has made good in his first test. This gives promise for the future, and the fact of technical training assures ease in breaking a new man into the business. You will find that a diploma is of little interest to others, but a likeable personality is a passport good for life and in all countries. In time you are to discover that tact and diplomacy solve more problems than engineering formulas. That a memory for names and faces will help you more than one for minerals and rocks. Sooner or later you will know that good sense, that ability to decide which of any two things is the more important, is an asset beyond price. You will awake to the fact that valuable as is skill in the higher mathematics, it will never push you to the front like the ability to write a letter which will really do its work. How will you deal with people if not through language, that means by which your thought and will may reach the consciousness of others, that delicate and subtle medium necessary for the simple affairs of daily life, yet capable under a master’s touch of swaying a multitude, of moving the world? How far have you learned its use? You have studied the reactions of chemistry, but how much have you learned of those subtle human reactions which break down indifference and create friendship?

The technical side of a mining engineer’s work is, and must remain, its distinctive feature. Next to the fundamental requirements of life, its importance is conceded by all. Not only is it necessary for him to shape his social qualities and general attainments upon broad-gauge lines, but it is well to recognize that the technical knowledge demanded by the mining world is broadening. The single specialist of former days is now under a disadvantage.

The mining engineer will always owe to his profession more than he can give, and the motives of obligation as well as those of policy, impel him to do all in his power for its welfare. This duty is the more imperative because it is a young profession, hardly more than a generation old. It has only of late been generally understood by the business world. During its growth, with advancing recognition, the professional spirit has steadily increased. The American Institute of Mining Engineers was the first and the most powerful means of collecting and uniting a number of scattered specialists into a self-conscious profession. Its great and long continued work has been ably seconded by numerous other engineering societies throughout the world. But what is not so clearly recognized is the remarkable work of the mining journals in developing the professional spirit of engineers and the feeling of fraternity among them. Their prompt and thorough collection of news from the remotest mining districts, the eager search for scientific and technical knowledge, their interchange of views; these have been doing a constructive work for the mining world of which it is as yet but feebly conscious. Today
these journals stand foremost among the forces which are welding mining engineers into closer relations with each other and with the business interests which they serve.

The growth of professional unity and interdependence has also been fostered by the continued spread of the modern idea that an engineer has more to gain than to lose by exchanging technical information with others. He parts only with what a single man can know, he receives the knowledge of a thousand men. A profession becomes powerful and is able to second individual effort only in proportion to the growth of the fraternal and helpful spirit. It is the policy, as well as the duty, of every true engineer to recognize this and to use his best efforts toward that end. Throughout your career aid your profession, its schools, its associations, its journals, and its members; and for every hour, for every dollar, you give it, you will receive a hundred fold.

There are men who shut themselves up, and out of their inner consciousness evolve great inventions or books. Occasionally a man will go into the wilderness and discover a mine. But such individual play has relatively small chances. The real business of the world is done by team-work, by innumerable bodies of men, each of which is under some kind of organization to combine its units into an efficient human machine. Every such machine, whether it be a base-ball nine, a section gang, the force of a great steel plant, a railway system, or an army, works with some irregularity. The individuals who compose it have human weaknesses, and the results are friction, loose-joints, lost motion, and sand in the gears. Nevertheless, the outfit goes creaking along, and usually gets there, often to its own surprise. There are weak points not only on the human, but also on the technical side of every business. Moreover, methods, processes, and machines are constantly changing. These conditions, the imperfection of technical methods and the faults of human organization, will provide your openings. It is because of them that the world is so full of opportunities for men who have the combination of sound technical training with good sense. When, therefore, you hold a job, do not waste time in complaints and fault-finding. You will continually see waste and loss, things which are wrong, things which need improvement. Others see them, too. If you have sense you will notice everything, but will keep quiet until the day when your advice will be asked. Some day you will be given charge of a piece of work, of a few men, and may then bring out your ideas by doing this work better and more cheaply than before. While you are in any business organization, be loyal to it, hold up the hands of those above you, and keep your own work as free as possible from the faults you notice elsewhere.

Throughout your career you will make errors and have occasional bad falls. Avoid the delusion that such occurrences are fatal, unless you fail to learn its lesson, and allow it to weaken your courage. Some of the most successful men I have known had failed so many times that they stopped remembering. Bear in mind the Arizona epitaph, "Life ain't in holding a good hand, but in playing a poor one well." Under normal conditions your status will long be simply that of the human animal struggling for the existence of self and family, differing from other animals only in its peculiar environment. The struggle for existence is your first duty, and may long demand your whole attention. But for those of you who respond to the spirit of the age, the time should come, by middle life if at all, when your eyes will be lifted from the details of self-seeking. You will suddenly become conscious of the great human organization of which you are a part, and of your relations to it. Thenereorth a part of the awakening soul of humanity you will see through the surface and into the injustice and unhappiness of the world around you.

**Deposits of antimony** on Coyote creek, in Garfield county, southern Utah, have been worked spasmodically since 1880, and it is reported that more than $100,000 worth of ore has been shipped from this region. The rise in the price of antimony in 1905-06 led to renewed activity, and 255 tons, part of which came from Utah, was mined in this country in 1906. Coyote creek, a branch of the east fork of Sevier river, occupies a short narrow valley in the northwestern part of Garfield county, in the high plateaus of Utah. The antimony camp is about 40 miles by road southeast of Marysville, the terminus of the San Pete & Sevier branch of the Rio Grande Western railway, and stands at an elevation of about 7000 ft. above sea-level. The ore consists of stibnite and its oxidation products. In the early days attention was given chiefly to the lenses of ore, which carried between 50 and 90% of antimony. The known lenses have all been worked out. At present no large bodies of stibnite are in sight, but in the dumps of the old prospects and in the tunnels there is a great amount of low-grade ore. A large concentrating mill has recently been erected and it is proposed to make star metal on the property.

**Diamonds in Arkansas** constitute the subject of an article in the Bulletin of the American Institute of Mining Engineers by George F. Kunz, well known as the gem expert of Tiffany & Co. Up to date 140 diamonds, aggregating 200 carats, have been discovered, the largest weighing 6½ carats. All were associated with a peridotite intrusive, and one stone was found 12 ft. below the surface imbedded in the igneous rock, proving that this was the original matrix. Lithologically the rock is almost identical with the diamantiferous peridotite of South Africa. The igneous intrusive has come up through the Carboniferous and Cretaceous quartzites and sandstones, and there is no evidence of high temperature having accompanied the eruption, the adjacent sedimentary rocks showing no contact metamorphism. Further exploratory work is in progress.

**Bessemer steel** was first used in America by the Pennsylvania Railroad Co., in 1863. The steel was employed in making locomotive boilers, but proved to be too hard and brittle, having an elongation of only 7 to 10 per cent.
MINING AND METALLURGICAL PATENTS.
Specially Reported for the MINING AND SCIENTIFIC PRESS.

The herein described rotary furnace, applicable for use in roasting ores and the like, comprising an ore chamber, the floor or hearth of which consists of a rotary central portion, and a surrounding annular portion which is stationary; a series of obliquely set scrapers, arranged above the central portion of the hearth and adapted to work the ore gradually toward the periphery of the latter, and one or more scrapers, arranged above the annular portion of the hearth, attached to the central rotating portion and adapted to sweep the ore in a circumferential direction toward the outlet orifice in the floor of the stationary portion, the furnace gases being caused to circulate both above and below that portion, substantially as herein described.

The method of treating ore containing copper and iron in non-metallic form to recover the copper, which consists in first subjecting the ore under reducing conditions to a temperature that will reduce metal producing constituents to a metallic state, and thereupon subjecting the reduced ore to a higher temperature sufficient to render fluid the copper constituent without melting the metallic iron constituent, and causing the said constituents to separate from each other.

APPARATUS FOR CONCENTRATING ORES.—No. 890,007. Ernest Wurdack, Baxter Springs, Kansas.

An apparatus for concentrating ores comprising a trough-shaped receptacle pivotally connected at its front end to a support, means for introducing the ore into said receptacle, a member traveling through said receptacle for separating the metallic particles of the ore from the gangue, means for moving the rear end of said receptacle downwardly so that said traveling member will always have a level surface to operate on, and automatic means actuated by the downward movement of said receptacle for cutting off the supply of ore to the receptacle and for discharging the contents of the receptacle; substantially as described.

PROCESS OF RECOVERING COPPER FROM COPPER-BEARING SOLUTIONS.—No. 890,857. Luis Amenábar, Coquimbo, Chile.

The process of recovering copper from a copper-bearing solution, which consists in subjecting the solution to the electrolytic action of a current of great density while in a circulating system in which the solution is brought into and removed from the field of electrolytic action a number of times.

In an ore-smelting furnace, the combination of a carbonaceous-fuel-burning furnace, an ore-stack, a chamber beneath and of greater cross-sectional dimensions than the stack, said chamber having a roof from which the stack rises and through which it discharges into the chamber, and a flue-forming neck leading from said fuel furnace, at a point about midway between its upper and lower ends, into said chamber and stack near their junction, for the purpose set forth.

In an electric furnace, electrodes, means to produce an arc between the ends of the latter, a hearth adjacent the arc gap between the electrodes but not immediately below the same, means to prevent material fed thereon from coming into contact with the arc ends of the electrodes and means to spread the arc over the hearth.
MINE REPORTS.

WAHI GOLD MINING CO., LTD., NEW ZEALAND.

The Waahi Gold Mining Co., Ltd., reports for the year 1907, that there were treated in its reduction works 35,974 tons (of 2,000 lb. dry weight) of ore, and that the gold and silver sold realised £387,485. This amount, together with £10,099 received as interest, makes the total gross revenue for the year £38,583. The expenditure in New Zealand and London, including development work at the mine, amounted to £237,074, leaving a gross profit of £530,910, as compared with £502,973 in 1906. This sum, added to the balance of £18,175 brought forward from the preceding year, gives a total of £249,068. Out of this the directors have provided £53,299 for sinking shafts, new plant, and machinery, as detailed in the balance sheet, as against £19,110 last year, and have written off 10% depreciation on plant and machinery, amounting to £35,012, as against £23,170 last year. The dividends paid, free of income tax, amounted to £22,339, being an excess of £24,785 over dividend distributed in 1906. The sum of £31,895 has been reserved for income tax in London and New Zealand for the year 1907. After these appropriations, the balance remaining to the credit of revenue account on December 31 was £206,451, which the directors recommend should be applied as follows:

To payment of a bonus of 3s. per share... £74,366
To be carried to reserve (making a total reserve of £149,090) 10,099
To be carried forward 22,155

Total...£206,451

The bonus now recommended by the directors makes a total distribution of 16s. per share, or 80%, in respect of the year 1907. Since the date of the accounts to March 21, 8,366 tons (of 2,000 lb.) of ore have been treated, yielding £204,951, and a dividend of 3s. 6d. per share was paid on March 2, absorbing £58,785. The directors propose to pay a similar dividend of 3s. 6d. per share on June 1, 1908, at the same time that the bonus of 3s. will be payable.

Further additions have been made to the ore-reserves, which on December 31 were estimated at £2,995,797 short tons, as compared with 1,029,655 short tons on December 31, 1906. The Royal lode was driven east on a distance of 789 ft. Of this distance, 406 ft. was driven east during the year, 306 ft. according to the cross-cut from the No. 9 shaft cross-cut, in ore varying in width from 1 to 25 ft., and in value from 1s. 9d. to £1 13s. per ton. West, 365 ft. was driven, in ore varying in width from 14 to 22 ft., and in value from 1s. 1d. to £2 8s. 11d. per ton. The total distance driven on the Royal lode at the eighth level to December 31, 1907, was 1425 ft. The Empire lode was driven on for a distance of 657 ft. to the west, making a total distance of 1044 ft. from No. 4 shaft, northwest cross-cut. From a depth of 285 to 685 ft. the lode varied in width from 7 to 39 ft., and in value from 5s. 9d. to £2 8s. 10d. per ton. The Marsha lode was cut at 581 ft. in the northwest cross-cut from the No. 4 shaft, and proved to be 110 ft. wide. The vein was driven on for a total distance on the northwest section of 1176 ft.—436 ft. east, and 740 ft. west of the main cross-cut. On the north section the vein was driven on for a total distance of 952 ft.—616 ft. east and 336 ft. west of the main cross-cut. The total length of vein driven on the eighth level was 1256 ft. The values at the eighth level on the Marsha lode show a falling off as compared with the level above, although the width has been fairly maintained. The Welcome lode was cut in the cross-cut from No. 2 shaft, and the south section met at 64 ft. from No. 2 shaft, proved to be 45 ft. wide, 25 ft. of which was worth £1 3s. 5d. per ton. The second strike of the vein met at 160 ft. from No. 2 shaft was 20 ft. wide, worth £2 5s. 2d. per ton. At 50 ft. west of the No. 2 shaft cross-cut the vein proved to be 120 ft. wide, worth £2 4s. 7d. per ton, and at 100 ft. west it was 100 ft. wide, worth £1 10s. 9d. per ton. The Edward lode was followed to the south for a distance of 200 ft., in ore of excellent quality. This vein opened up in a highly satisfactory manner, showing a large increase in widths and values compared with the level above. At 150 ft. south of the Welcome vein junction it was 48 ft. wide and worth £9 12s. 6d. per ton. It is proposed to increase the pumping capacity at the mine so as to have reserve pumping power for lower levels, and the sum of £10,000 has been appropriated toward doing this work. In comparing the year now under review with the previous year, it appears that there has been an increase of 25,108 tons in the amount of ore crushed. The assay value per ton was 23 14s. 11d., which is 2s. 9d. per ton less than last year. The actual yield per ton for 1907 is £2 3s. 5d., as against £2 10s. 11d. last year. The working expenses, which were reduced last year, show a still further reduction. The tonnages crushed at the three mills, together with the totals crushed during 1906, were respectively as follows:

<table>
<thead>
<tr>
<th>Year</th>
<th>Total Crushed</th>
</tr>
</thead>
<tbody>
<tr>
<td>1907</td>
<td>25,108 tons</td>
</tr>
<tr>
<td>1906</td>
<td>25,108 tons</td>
</tr>
</tbody>
</table>

The increased tonnage during the year 1907 thus amounts to 25,108 tons. The total average number of stamps running during the year, exclusive of the three ones at Christmas, during which the mills were stopped, was 31,458 out of 330 stamps. The total average duty per stamp per diem was 3,794 tons, representing an increase of 0.29 ton per stamp compared with the previous year.

The total extraction obtained during the year, according to assay, was 89% of the gold and 10.5% of the silver content. This is an improved extraction, as compared with 1906, of 0.5% of the gold and 4.2% of the silver. The estimated value of bullion scraps, zinc slimes in precipitator boxes, and concentrate in treatment plant on hand shows an increase of £3,885 17 shillings.

BOOKS RECEIVED.

This work was prepared at the instance of the Carnegie Institution of Washington, to constitute a part of the economic history of the United States. It is accordingly distinctly a historical work, and the adaptation of magnetic concentration to zinc ores. Statistics of production, consumption, and price are given, and a most illuminating summary and discussion of the history of tariff legislation on lead since 1789, constitutes a most interesting chapter. The book is packed with information, and is eminently readable. It does not in any sense replace the treatises on zinc previously prepared by the same author, nor does it take the place of a guide to the metallurgy of the metal. It is such an excellent and well-informed progressive business man could read with profit and pleasure, and which any technical man connected with lead and zinc production cannot afford to neglect.

William Kent has resigned from Syracuse University and will devote the year to the revision of his well known 'Mechanical Engineer's Pocket Books.'

The ENGINEERS' CLUB, of Philadelphia, announces that its address is changed to 1317 Spruce St., Philadelphia, Pennsylvania.
RENEWABLE SEAT RE-GRINDING VALVES.

The Lunkenheimer Co., Cincinnati, Ohio, has designed the valve shown in sectional view herewith for the benefit of those preferring a renewable seat re-grinding valve. This valve differs from the Lunkenheimer regrinding valve only in the construction of the disc and seat. The disc, 12, is provided with a projecting ring, which enters the valve-seat ring, 13. Its principal function is the preservation of the seat, which is accomplished in a two-fold manner. First, as it enters the cylindrical part of the seat it deflects the current of steam from the seat-ring face, thus preventing the wire-drawing which would otherwise occur.

This feature is especially important should the valve be left partly open for any length of time. Secondly, the seating surface is kept free from scale and grit by the action of the thin current of steam discharged over it as the disc is brought home. Another function of this ring is the prevention of waterhammer which is caused by the sudden admission of steam, for it will readily be seen that no matter how quickly the hand wheel may be operated the flange will only permit the steam to enter gradually. The seat, 13, is renewable, and can be removed from the valve-body by using a flat bar to engage the lugs on the inside of the ring. The Lunkenheimer Co. calls particular attention to the fact that the seat may be re-ground a number of times before it is necessary to renew it. Not only is the seat renewable, but all of the other wearing parts, including the disc, can be renewed if necessary.

The hub is securely held to the body by means of a union-ring, owing to which it is impossible for the hub and the body to become corroded together, as the thread which holds the union to the body is protected at all times from the action of the steam, the joint being made between the flange on the hub and the neck of the body. This connection also acts as a tie or binder in screwing over the body, and tends to strengthen the valve. The stuffing-box can be repacked under pressure when the valve is wide open, as a shoulder on the stem directly above the threads forms a seat beneath the stuffing-box. All valves above the 

1/2-in. size have a clod-follower in the stuffing-box. Lunkenheimer renewable seat-valves will stand 200 lb. working pressure, and are made in both screw and flange ends. Up to 1 1/2-in. inclusive, valves are furnished with hexagon bonnet rings; above 1 1/2-in., round slotted rings are sent. Either style of ring can be had for any size of valve without extra charge. English instead of American standard pipe-threads and flanges are furnished when so ordered. The valves are also made with 'navy-standard' flanges, and brass hand-wheels. With the exception of the seat rings these valves are made entirely of the highest grade of bronze, according to the formula specified by the U. S. Navy. The seat-rings are made of hard, close-grained nickel, and will permit of re-grinding many times over. To re-grind, unscrew the union ring, 5, take the trimmings from the body, and place a little powdered sand or glass and soap or oil on the disc, inserting a wire or pin through the slot in the disc locknut and rotate in the stem. Then replace the trimmings in the valve-body and re-grind, leaving the ring unscrewed, so that the hub will rotate in the body and act as a guide for the stem while re-grinding. The Lunkenheimer Co. has issued an attractive booklet describing this new valve which will be sent on application.

RECENT ELECTRIC LOCOMOTIVES FOR MINE HAULAGE.

The extensive use of electricity as a motive power in mine haulage is proof that its employment has passed the experimental stage. The electric locomotive is compact and simple in construction, and does not impair the sanitary condition of the mine. The same source of power that drives the locomotive can also be used for operating fans, pumps, hoists, and other machinery. By combining the power-requirements in this way, the load fluctuations are reduced and the entire plant can be more economically operated. The accompanying illustration represents a locomotive for mine service recently built for the Liberty Bell Gold Mining Co. of Telluride, Colorado, by the Baldwin Locomotive Works, and equipped with electrical apparatus supplied by the Westinghouse Electric & Manufacturing Co. It is an exceedingly compact machine, having an approximate weight of 7000 lb., and designed for a track gauge of 2 ft. The width over all is 2 ft. 11 in., the height 3 ft. 7 1/2 in., and the length 6 ft. 6 in. The frames, which are of cast-iron with bumpers of the same material, are placed inside the wheels. The wheel-base is 2 ft. 3 in., and the wheels are of chilled cast-iron 20 in. diam. The locomotive is of the single-end type, and the equipment includes brakes and sanding devices on all the wheels. Both pairs of wheels are driven through one motor, which is of the K-7 type, suitable for 220 volts pressure, and connected to the axles through double-reduction gearing. The motor is carried on a cast-steel cradle supported directly on the axles. It is placed above the wheels and midway between them, and is geared to a shaft placed immediately beneath it, which shaft is in turn geared to both axles. With this arrangement the gears are held in correct alignment while running over rough tracks, and there is an equal distribution of power between the two pairs of wheels. The motor is covered by a sheet-metal hood which may be opened on top, making the equipment readily accessible. The flexibility of an electric power system is one of its chief advantages, and in the case of the locomotive this is a feature of great importance, and these motors can be designed to fulfill practically any conditions existing in underground work.
STORAGE MACHINE.

A beautiful, efficient, and remarkably flexible machine on the flight-conveyor principle for storing and handling ores, coal, and other products, has been developed by the Hamilton Manufacturing Co., of Columbus, Ohio. The accompanying illustration shows an exceedingly powerful machine in use at the storage yards of the Illinois Steel Co., at Stockton, Ind., handling coke. The coke pile is 35 ft. high. On the 100-ft. platform are stored some 100,000 tons of coke, which this machine is employed to load and unload. In one day's run, 4½ hours' total time, the machine loaded 24 steel hopper bottom cars, containing in all 732 tons of coke. Three men are needed to operate the machine, the capacity of which is about 3000 tons of coal daily. The cost of loading is about 1c. per ton. Hereinafter in order to economize, it will save the cost of hand labor of $100 per day. It is operated on its own track by its own power. The gathering conveyor is mounted to swing universally about the head shaft, its nose continually resting upon the platform, so that the scraper conveyor is able to pick up material from any part of a platform 100 ft. wide. The material thus carried up is delivered to a second conveyor which swings about the head shaft on a turn table. It will deliver material into cars at either side of the platform, or, in fact, at any point that may be desired, within its radius. As the latter conveyor may be raised and lowered, it will stock material to a height of 35 ft. Material can be transferred both into and out of storage, at the rate of four to six tons of bituminous coal per minute, and as the speed of the gathering conveyor is very low, it accomplishes this without damaging the material. The Illionis Steel Co. credited the machine with a saving of 5½ in the condition of the coke as delivered into the railway cars, thus amounting to a saving of 25c. per ton. On the basis of 100,000 tons per day, such an economical unit will save the cost of the machine in one year. Aside from the machine itself, the track on which it runs, and the trestle at the side of the yard from which the material is dropped to the platform, there is no investment in plant. When additional storage is called for, all that is required is to extend the track and trestle, for the machine moves as it builds or re-loads the pile all along the length of the platform. In other words it has the elasticity of a locomotive crane, and the capacity of a traveling bridge, without the limitations of either, while its first cost is stated to be 25% less than that of any other system having equal capacity. The Hamilton Co. builds different sizes between their pit-car loader, having a capacity of 30 to 40 cu. ft. per minute, and the large machine running as high as 360 cu. ft. per minute. The mine-car loader, built on the same principle, is adapted to tunnel work, as well as to other situations underground.

ANOVEL SIDE-DUMP MINE CAR.

An order has been completed by the Arthur Koppel Co., of Koppel, Pa., for 200 mine cars for the Copper Queen Consolidated Co., Bisbee, Arizona. The cars are especially designed for that company, and had a capacity of 21 cu. ft. and a gauge of 20½ in. The side door and end-plates are built of ¼-in. steel and the floor-sheets of ½-in. steel. The dimensions are, length over all, 6 ft. 1 in.; width, 2 ft. 8 in.; and height, 3 ft. 10 in. The wheel-base is 21 in., which allows it to take curves of as small a radius as 15 ft. with ease. Spokes wheels of cast steel are used, these being equipped with Siamese roller bearings, which reduce the tractive-power and lubricating expenses materially. A unique feature of the car is the arrangement of the door-operating mechanism. This is worked by a ‘trip’ placed between the rails at any point on the line where it is desired to discharge the car. This mechanism is secured to the under frame instead of to the floor of the car. The principal advantage of this arrangement is that there are no rivet-headers or bolt-headers on the inside face of the floor-sheets to interfere with the discharge of the load. This was a requirement made by the Copper Queen Co. The doors are automatically re-locked when they fall into posi-

COMMERCIAL PARAGRAPHS.

S. F. Shaw has opened an office as mining engineer at 737 B St., San Bernardino, California.

Mark R. Lamb, Mexico, D. F., has recently closed a contract for a 150-ton Moore filter for a mining company in Pachuca.

Fairbanks, Morse & Co. announce that they have moved into their new general office building at Wabash Ave. and Elzene Place, Chicago.

The Colorado Iron Works, Denver, announces that James P. Evans has been appointed to the superintendent, a position made vacant by the death of J. H. Morcom.

C. Kemble Baldwin has severed his connection with the Robbins Conveying Belt Co., and is now chief engineer of the Robbins New Conveyor Co., with offices in Chicago.

Arthur Koppel Co., San Francisco, have in the last few days shipped several miles of portable track consisting of 12-lb. rails. The order also included a number of cars and switch sets.

The C. W. Hunt Co., New York, has issued Pamphlet No. 681, illustrating and describing some of the labor-saving machinery manufactured by it, with special reference to coal handling and conveying.

THE COPPER MARKET shows a healthier tone, electrolytic having advanced slowly from 12.50 cents on July 1 to 12.63 by the end of last week, at which point it has since remained. Curtailment of the Montana output in June owing to flood-damage would suffice to explain this condition, anticipated copper stocks being short about 13 million pounds.

A SPIRIT OF FRATERNITY among men could not well proceed from a better source than common love for the alma mater that prepared them to enter the battle of life equipped for successful effort. This spirit brought forth good fruit at the recent annual dinner of the alumni of the Royal School of Mines, resident in South Africa, through the appointment of a permanent committee to further the interests of those united by this bond of fellowship. A pleasent feature of the arrangement is the provision made to welcome new arrivals. Any alumus proceeding to South Africa for the first time is requested to communicate with the secretary, Mr. C. Baring Harwood, at the Rand Club, Johannesburg.

CREOSOTED TIMBER is not used to any large extent as yet in mining operations. This seems to be due in part to lack of interest in or understanding of the benefits to be gained, and also from the desire of managers to keep down present costs, regardless of what the balance sheet five years later might reveal. Any mine which has expectations of surviving for a period longer than five years cannot afford to use untreated timber in shafts, gangways, and other openings intended to be kept open for traffic. The great majority of mines erect works before a justifiable development of ore has been made, and exist in a precarious condition, with ore-reserves inadequate to admit of the introduction of economics which could be practised were it possible to take a sufficiently long look ahead. But timber is not only increasing in cost; it is destined to become practically prohibitive for use in our prevailingly reckless and uneconomic manner.

Overthrowing Railroad Monopoly.

We recently called attention to the striking fact that New England and the Pacific Coast resembled each other through an unfortunate likeness of exorbitant trust-made freight rates, under which each suffered repression of industrial growth. In New England the average freight rate per ton mile was 1.17 cent in 1907, while in the Pacific States it was 1.25 cent. Every other section of the United States enjoyed decidedly more favorable conditions. New England has been the home of staunch
patriots, and has been particularly distinguished for the display of that more restricted form of devotion to public welfare known as civicism. The highest type of civicism would, of course, result from the simple application of the golden rule. It is believed to be an excellent rule, though quite generally disregarded, and not sufficiently practiced to have yielded extensive data concerning its working effect. As a substitute therefore, we resort now and then in a spirit of reform to compulsory methods of making the other fellow do unto us as we ought to do unto him. In this brief argument we have gathered together the root, trunk, and branch, and a clear vision of the nourishing soil, of what we term paternalism. This does not mean always to pamper and coddle; in fact, since the wiping out of vast legalized monopolies in England, such spoiling of the Anglo-Saxon child has been done under the guise of tariffs and subsidies. But the true paternalism is that which looks after all the children, and Massachusetts, having seen that individual civicism could not protect the community from being strangled by a dominating railroad system, resorted to collective civicism with such effect that a new era is actually dawning. Although a corporation is a legal person, it is not recognized in law as an entity with the privileges pertaining to individual liberty, which is particularly true of a public-service corporation. It is subject to higher restraints. The argument for such distinction need not concern us here. It is a fact, and the asserted right of corporations to freedom of action and secrecy of method, is being more extensively invaded year by year.

Massachusetts has been suffering an industrial depression for more than a decade that has been like the extension of paralysis through the community. Railroad rates have been simply intolerable and discriminations against New England ports in favor of New York have been more pronounced. The New York, New Haven & Hartford railroad gradually acquired ascendancy over all the great arteries of traffic. The people demanded reciprocity with Canada as a relief. Meanwhile the railroad monopoly was preparing to eat the apple of reciprocal trade, and it was doubtful whether there would have been any core left for the other boy. The acquisition of a control of the Boston & Maine with its ramifications into Canada placed the monopoly in a position to reap the chief benefits that might accrue from a reciprocity arrangement. The railroad finally received its rebuke. An act, known as the Cole bill, was passed by the Massachusetts legislature, under which the Attorney General may secure an order of court restraining a corporation from participating in the dividends upon stock held by it in another corporation. The remedy is simple and so effective that the New York, New Haven & Hartford Railroad Company is selling its holdings in the Boston & Maine, and in the electric trolley lines throughout the State. Competition will consequently be revived, and commerce, freed from burdensome restrictions, can move again, allowing the dormant activities of the people to re-awaken.

This little chapter in politico-economic history is instructive. It shows what can be done to give every citizen the even chance which is needed for healthy industrialism, if the people will rally to the primaries, and do their civic duty in overwhelming bossism so as to elect at least a working-majority of honest men to the Legislature. Industry is throttled in the West as it has been in New England; our mines have been robbed, and large numbers of properties that should have swelled the mineral output are lying idle, because of the crushing freight-tolls exacted by the transportation monopoly. New England is achieving emancipation which will doubtless extend to all phases of her commercial life, for the taste of freedom creates a larger appetite. Perhaps the spirit of independence in the West is not so far extinguished but that we may hope soon to see an emulation of the courage and practical wisdom of the awakening New Englander.

Professional Ethics Again.

THERE is encouragement to be drawn from the fact of a growing interest in the ethical problems involved in a proper discharge of duty by the mining engineer. The present is a peculiarly appropriate moment for penitential reflection, and this leads inevitably to ethical considerations. Many things have fallen out otherwise than the public hoped and anticipated; the mining world has passed through experiences chastening to its spirit, and not a few men are wondering how far depreciation of reputation has proceeded. Questions of abstract right accordingly assume special interest at such a time, both for the public and for the engineer. The Financial News, of London, has referred to recent expressions of opinion in these columns with that sort of criticism which proves that the question is not academic, but vital and pressing for solution. This appears further from the fact that our contemporary promptly separates the general principle involved from the specific case which we discussed. Of course that materially enlarges the field; it even expands it far beyond the limits examined by The Financial News. It is too large a subject, for that matter, to be expounded with any pretence at finality by an individual. It must be determined by the consensus of opinion of a representative body of those chiefly concerned, and we are pleased that the recently organized Mining and Metallurgical Society of America proposes to endeavor to formulate rules which will be conclusive, and which shall become recognized as the standard of professional custom to which all mining engineers must conform in order to remain in good standing. It is not an easy task, and we foresee friction enough to generate a high temperature. One difficulty is that some of the questions concerned in making any code of so-called professional ethics, are only distantly related to pure ethics. They represent matters of expediency and good form, but necessary as a means of protection to the public and to the engineers themselves. There is no moral wrong in an engineer holding an interest in a property which he has examined; there is not
even any moral obligation which could require an honest man to decline contingent fees, granting that he believed his judgment would not be warped by the self-interest at stake. It is most probable that he could not make such an examination without bias which might work injury to future investors. It this could be proved, then moral rectitude would preclude acceptance of an engagement on such a basis. It would certainly bias the minds of the vast majority of men to the point of incapacitating them for accurate examination, critical use of data, and sound justifiable conclusions. But a few men may be found who could face the utmost temptation of self-interest without change of heart-beat or deflection from the mathematical line of absolute integrity of thought and motive. Therefore it is not a case of pure ethics; but in deference to the prevailing Atlantic weakness, and to the need of so protecting the investing public that the mining engineer may, in furtherance of his ultimate pecuniary advantage, win confidence and have his services regularly esteemed and well remunerated, the matter assumes importance as a necessary part of a code of professional ethics. An engineer should not work for contingent fees. We know that, because of the errors it continually leads to, and the unscrupulous class of promoter with whose operations the practice is perpetually associated. It is a custom that prevails in connection with those evils that walk in the darkness within the realm of mine-promotion.

Since our esteemed critic chooses to depart from the specific instance calling forth our remarks, which was the justifiableness of the engineer, who had reported on the Yukon Gold properties, in selling his stock when the price soared to a speculative height, we will follow his lead. He declares, “it is difficult to see why any honest mining engineer should be required to hold his shares until his own estimate of value is actually attained by the shares, while a vendor of port wine for 'laying down,' who says that the wine will, within a certain period, double its value, escapes reproach, even though he does not keep the wine himself, instead of selling its potential betterment to other people. The greatest error of the early political economists was to assume that in all commercial transactions the whole advantage remains with the seller, and the entire loss with the buyer. It is not so. Any commercial transaction, conducted on the ordinary lines of fair-play, candor, and honesty, advantages both parties. A mining engineer may quite honestly believe that certain shares are worth £5, and that they will ultimately reach that price; but he is not necessarily a rogue because he sells at £3, for all that.” By no means; we quite agree. The first consideration, however, is whether the reporting engineer should have had shares to sell. Opinions differ, but we believe the final judgment will be that it is unprofessional. At present we are in a formative period; professional sentiment is growing, and the rule of propriety has not been rigidly drawn, largely for the reason that there has been no competent authority to draw it. Having the shares, he is entitled to sell to his advantage, retaining a perfectly clean conscience so long as he has not directly or indirectly manipulated or influenced the public to produce inflated prices. Our contention was that the price at which Yukon stock was selling was the result of misrepresentations, and was, to use the most charitable phrase, highly speculative. The public has its own logical habit of thought, which must be reckoned with whether philosophically defensible or not, and in this case it interpreted the sale of stock by the examining engineer as evidence that he also considered the prevailing market price unwarranted.

The wine was not ripening and gaining value. A company was in existence, costly to maintain, and the mines were producing nothing. Certainly the gold was not growing in the placers, but most assuredly large promoter’s profits were accruing, leaving less to go round at the prospective banquet of the stockholders. Most decidedly the wine was not improving. Leaving this aside, the argument is faulty because a mine is essentially subject to decline. Discoveries from time to time may demonstrate larger returns than were anticipated when the company was organized. If the original capitalization were conservative, such adventitious circumstances will, of course, augment the market price of the stock. But the maturity of a mining share is marked by its amortization, which may involve resurrection of the capital, or burial in the tombs of financial disaster. It is not like the ripening wine, in whatever light it be viewed. So we come back to our original statement that “if mining companies encourage their engineers to buy stock, they are estopped from complaining against the selling of that same stock whenever the price becomes inflated.”

The company should not encourage the engineer to become a stockholder unless it expects him to stake his whole future on the success of that enterprise. Then the reward must be adequate, and the engineer should definitely retire from general practice. We believe that in time laws will be enacted requiring endorsement by qualified engineers of mining stock offered for public subscription, and deharring from qualification any engineer holding present or prospective interest in the company issuing the stock. No standards of professional ethics have ever been established that have exercised any controlling or even important influence save through legal confirmation, and penal prescription. The status of the professions of the law, medicine, and architecture, reveal the force of this. Some professions do not seem to call for such restrictions, but the fact that both the mining engineers and the general public are keenly sensitive to the existence of conditions demanding a strict construction of the obligations of the profession, shows that it is not a trade, concerned only with skilful and conscientious performance of work, but that moral issues are involved in the functions of the mining engineer. These must be defined by those most competent to decide, and rules set forth. Then must follow the sanction and safeguards of law in order to render them of any effect as between practitioner and client and the public.
Personal.

W. S. Noves is in Oroville.
H. F. Fulton is in Montana.
Frank Proctor is at Globe, Arizona.
Samuel Newhouse, of Salt Lake, is in New York.
J. Parke Channing was in San Francisco this week.
T. A. Rickso will be in Fairbanks, Alaska, next week.
Albert Ladd Coley, of New York, is at present in London.
E. N. Atkins has been in Toluca lake the past week.
C. W. Doore, Jr., is now in charge of the Denver office of Spurr & Cox.
J. E. Spurr has been in Pima county, Arizona, in the interest of the Guggenheims.
Robert J. Coleman arrived in San Francisco from Denver, and has gone to Los Angeles.
Edmun Jerssen, consulting engineer to the Mines Exploration Co., is in San Francisco.
Walter W. Wishon has gone to examine the Lake Shore gold mine, in Madison county, Montana.
John Power Hutchins is in British Columbia, near Revelstoke, examining a dredging property.
Gardiner F. Williams has gone to South Africa for a brief visit to Kimberley and Johannesburg.
Jos. E. Settle, formerly manager for the African Gold Dredging & Mining Concession, has returned to London.
W. Arthur Sloan has been appointed chief chemist at the smelter of the Shannon Copper Co., at Clinton, Arizona.
E. C. Holden has been appointed to the professorship of mining engineering at the University of Wisconsin, at Madison.
J. M. Callow is in Juneau and the Yukon territory on professional business, and will return to Salt Lake the first week in August.
T. R. Drummond, formerly manager for the Dominion Copper Co. in British Columbia, has been appointed manager of the Cactus mine, at Newhouse, Utah.
Robert H. Richards is making a professional tour in Arizona, Utah, Montana, Idaho, and Colorado, and will reach Boston by the middle or end of August.
J. F. M. Rowers has returned to Los Angeles, California, from Grasselli, Indiana, where he was engaged in erecting the silver refinery at the works of the U. S. Metals Refining Company.
W. P. Miller, Jr., has resigned the management of the Cia. Minera de San Andres de la Sierra, Durango, Mexico, to operate the San Jose de los Llanitos mine at La Portilla, in the same State.
Fred Lyon, who was recently made assistant manager of the United States Smelting, Refining & Mining Co., has completed an inspection of the company’s property in Utah and is now on anilue mission in California.

L. Vogelestein & Co., New York, give the following figures of German consumption of foreign copper for the months January to May 1908:

<table>
<thead>
<tr>
<th>Tons</th>
<th>72,247</th>
</tr>
</thead>
</table>

Consumption of copper, 68,883

The consumption during the same period in 1907 was 47,030 tons. Of the above quantity 67,153 tons were imported from the United States.

Engineering Societies.

The American Chemical Society will hold its general meeting of the summer of 1909 in San Francisco. The exact date will be decided by the president and secretary.

General Mining News.

ARIZONA.

COCONISE COUNTY.

Martin Costello has foreclosed the first and second mortgages on the Copper Belle property, at Gleason. The amount involved is said to be in the neighborhood of $50,000. The sale of the property has been set for July 25. The output of copper for the Warren district, during the month of June, was approximately 500,000 lb. more than that of the preceding month, due to the increase of operations at the Copper Queen smelter, at Douglas, and at the Calumet & Arizona smelter. A Copper Queen output, of several thousand pounds in excess of the May production, and that of the C. & A., was 4,200,000 pounds.

GILA COUNTY.

The June production of Old Dominion was about 2,500,000 lb., approximately the same as that for May. Between 35 and 50% of this came from the company's own mines, and well over 35% of the entire smelter output came from the Globe district, the only foreign ores being about 100 tons per day of sulphide ore from California.

MARICOPA COUNTY.

James E. Cochran, of Bradford, Pa., has recently purchased the Buffalo mine in the Harshaw basin and will start extensive development. This mine, formerly known as the Jefferson, was worked by a Philadelphia company a number of years ago. There is a 90-ft. shaft.

PINAL COUNTY.

There is considerable activity in the Florence district, although most of it is only development work. The La Coronado property, which is being developed by Phoenix people with local capital, is about 18 miles north of Florence. Men are now at work following the vein into the mountain. At the Superior mine there are now 35 men at work, and arrangements have been made to increase this force as soon as there is room for more men. A large amount of ore has been blocked out and will be shipped before long. The Queen mine, on Queen creek, 25 miles north of Florence, is being developed by Globe capitalists. Twenty men are at work, with the formation getting more favorable all the time.

SANTA CRUZ COUNTY.

Nogales held a drilling contest on July 4, the conditions and results of which are given herewith, obtained through the courtesy of Wallace, Glore & Summerhayes, mining engineers, of that city. The following rules governed the contest: "Contest to be double handed, each pair to drill for 15 minutes exactly, changing as often as they desire. All steel to be 5/8 in. diam., measured at a point 2 in. back from the cutting edge of the bit. No swaged steel to be used. No credit for lost holes through breaking steel or chipped holes or other cause, except that if any pair drill through the rock they be to discount 2 in. and allowed to start a fresh hole, full depth of which will be allowed. Singing to be set by each pair to suit themselves." The purses amounted to $350, plus entrance fees, but minus the actual expense of getting the rock. The net purse was $393. The amount of entrance fee was not stated. The rock used was an especially hard-grained granite, with scarcely no mica. The contest was won by Dunn & Dally, of Patagonia, who drilled 33 1/2 in. and struck at the rate of 59.5 times per minute. Miller & Ryan struck at the rate of 87.5 times per minute, but drilled only 24 1/2 in., due to the fact that their steel was tempered too hard, and hence broke six times during the 15 minutes.

YAVAPAI COUNTY.

J. B. Tomlinson, controlling the Sterling properties, announces that it is his intention to move the present 20-stamp mill farther up the hill. A cyanide and slime plant suitable to the economic treatment of the ores, not only of his own, but other adjoining properties, is to be added.

With the large tonnage now opened in the Sterling and other adjoining properties, which cannot now be shipped at a profit, but which would be considered high grade under more favorable circumstances, the district will, with the new plant, soon rival other parts of Yavapai county in gold production. The Russell group of claims is particularly interested in this deal, as they and many others are tributary to the new mill. Last month's output from the United Verde Copper Co. mines was slightly in excess of 3,000,000 lb. of copper. The United Verde is mining from both of its shafts, one of which is 1000 ft. deep and the other about 500 ft. A large part of the production is coming from the 5th, 6th, 7th, and 8th levels. For a while the United Verde was turning out its copper without the use of roasting ovens, but these ores are now being utilized as formerly.

YUMA COUNTY.

(Special Correspondence).—A Los Angeles company, headed by George Mitchell, has purchased the Big Signal mine in the Wendendale district, and will, it is reported, erect a smelter at once. The property includes 100 claims and has extensive water rights. Fifty men are at work on the Cunningham Pass property, in the same district. A new boarding and bunk-house is being erected and at its completion 20 additional men will be put at work. Teams are hauling ore to the railroad at Wendendale. Parker, July 11.

CALIFORNIA.

CALAVERAS COUNTY.

The Mohawk mine, near Railroad Flat, has recently completed a test run of ore through its 9-stamp mill, and received returns of $25 per ton. The Mohawk shaft is a two-compartment incline 200 ft. deep. The Blue Bell mine, on the south fork of the Mokelumne river, a mile and a half from Glencoo, has been bonded to the Golden Era Mining Co., of San Jose. A 40-stamp mill will be erected and active development undertaken. The Matson custom mill on Cedar gutch is running a 40-ton mill test of ore from the Occidental mine.

NEVADA COUNTY.

(Special Correspondence).—Considerable development work is going on at the Kenoshia mine. The shaft is still going down with drifts showing excellent ore on the 200 and 300-ft. levels. A small force of men is employed. At the Posey Canyon, driving is under way to develop the channel recently struck by the raise from the adit. It is reported that a small mill will shortly be erected. William Grant is superintendent. The lower portion of the Central shaft is being cleaned up preparatory to the cutting of a station at the 5460-ft. level. The working face at the Golden Gate mine has been reduced. The work of re-opening the Grey Eagle mine is under way. The sinking of the shafts from the adit on the two vertical veins has been commenced. Fifteen men are employed. Considerable activity is under way in the Washington district. The Yuba and Mayhert are operating a large crew of men and pushing active work. At the Red Ledge, where high-grade ore was recently found, development has exposed a promising ledge of good milling quartz. The Grass Valley and Nevada City districts are crowded with idle men. The present state of affairs is in marked contrast to a year ago, when it was difficult to secure enough men to keep the local mines running full-handed.

Grass Valley, July 13.

SAN BENEDICTO COUNTY.

It is claimed that vanadium of lead has been discovered on the Nolita vein claim, 7 miles north of Grass Valley. The claim is 3/4 ft. wide, and also assays 93 per ton in gold. The Hart Florence Mining Co. has started work on its Florence claim, and the Oro Belle Mines Co. will start some time during July.

SIERRA COUNTY.

The Messenger mine, near Mountain House, has been leased to W. H. Blalock, of Reno, who is now working five men at the property. A 3-stamp mill gives assays of $9
MINING

coming wholly The to blind to A. short is Co. The 3 Two will preparing the its nearly extraction. to their expectations, the the streak B. being sending 10-year J. wide, under W. 700 Co., two from E. The The which ly of of advanced of Eastern a argon, is inadequate. This adit, handled at Georgetown is 3, recently passing over to a syndicate of $100 per ton could not be handled at a profit. However, under the prices now being paid for the basic metals, as well as the methods of treatment, the entire product will be available for extraction. Extensive development is planned in the exploitation of virgin territory. B. J. Mar- telon, of Silver Plume, is in charge of the property. —Two shifts of miners are now employed at the Doris adit holdings. These miners recently passed over to a syndicate of Eastern men, headed by John Larsen, of Idaho Springs. It is reported that a new and modern compressor plant will be installed at an early date, as the equipment now in use is wholly inadequate. The adit, now in 3000 ft. is to be advanced for an indefinite distance. Stopping is under way upon the Cram vein cut 2400 ft. from the portal. A body of ore is being followed that may amount to a tonnage of $100 per ton. The property is situated in the heart of Georgetown, on Saxon Mtn.—The strike made in the heading of the Scepter adit two weeks ago, is coming up to expectations, the streak having widened from 8 to 12 in. As soon as the heading has been driven 35 ft. stopping is to be started. This property, including the Sunburst and Anton recently passed over to the Stewarts-Hill Silver Co., the consideration being $150,000. A compressor plant is to be installed soon, at the Scepter workings. M. J. Riley is resident superintendent.—The Santiago, East Argon- tine, is sending out a heavier tonnage of ore than at any time during its history. On the 5th level, Nulsh & Co. are carrying a spore on a streak of smelting ore that has been over 889 per ton in gold, silver, and copper, the last named metal running as high as 15%. Allgood & Co., who are at work on the level above, are stopping on a streak of mineral that is from 18 in. to 3 ft. wide, the first class milling $45 per ton.—One of the most im- portant mining deals which has been put through this season is that of the Waldorf Metals Co., for the purchase of the Huckleberry group of claims, West Argentine, and a 10-year lease on the Independence, Wheeling, and part of the Commonwealth mines in East Argentine, all the property of the Waldorf Co., M. Co. The purchasing company will extend the Wilcox adit an extra 450 ft., or until the Wheeling-Independence vein is cut, and thorough- ly developed the latter, as well as the Commonwealth, which has already been intersected. A cross-cut is to be run from the base of the hill to intersect the Huckleberry vein. It will be necessary to drive only 200 ft. to reach the objective, and a depth of nearly 1500 ft. will be secured. Large capital from Kansas City, Mo., is to be invested in this enterprise. D. F. Sprouse, of Georgetown, has been ap- pointed manager.—Miller & Jacobs, leasing on the Tobin, have uncovered a 10-in. streak of polybasite, which gives assays varying from 350 to 400 oz. silver per ton. Stopping is under way and a carload is to be sent out within two weeks.—E. W. Shepard, leasing on the Wolverine, will commence drifting in a few days. This creek is stopped by the 5-in. streak of gray copper that shows assays running from 400 to 700 oz. silver.—H. J. Crist, leasing on the Choc- taw, Saxon Mtn., is meeting with gratifying results, hav- ing shot into a 4-in. streak of $72 silver-lead ore. The discovery was made 18 ft. from surface. The mine was a former heavy producer.—A. J. Winnegang, owner of the Elise group of four claims on Alpine Mtn., expects to start work in the course of a few days. The holdings are undeveloped, but the veins run parallel with the Sporting Times, which is producing high-grade gold-silver-lead ore.—The Terrible still continues to send out more ore than any mine surrounding Silver Plume. A series of lessees are at work on the 14th level and all are stopping on streaks of mineral that are from 8 to 20 in. wide. This is the deepest worked mine in Clear Creek country. T. J. Wadsworth, of Denver, has secured an option on 1000 ft. of the Stevens mine, West Argentine, as a deal is now pending for the transfer of the property. A heavy output has been made during the last three months.—Another strike is reported from the Colorado Central, Leaveyworth Mtn. In extending the east drift a streak of ruby silver 16-in. wide has been uncovered that assays from 425 to 450 oz. silver. It is reported that F. A. Maxwell, the lessee, has secured control of the Husted mines which adjoin to the west. Georgetown, July 14.

COLORADO.

CLEAR CREEK COUNTY.

(Special Correspondence).—The Shively adit, being driven to intersect the 500-ft. level of the shaft workings, reached the objective July 3, with the shooting of the last round of holes. This was a most important piece of mine- ing engineering, and it means that one of the former heavy producers of the Georgetown district will be reju- venated. During the early history of development, large bodies of low and medium grade ore were left in the workings, and the material assayed that material at $100 per ton could not be handled at a profit. However, under the prices now being paid for the basic metals, as well as the methods of treatment, the entire product will be available for extraction. Extensive development is planned in the exploitation of virgin territory. B. J. Mar- telon, of Silver Plume, is in charge of the property. —Two shifts of miners are now employed at the Doris adit holdings. These miners recently passed over to a syndicate of Eastern men, headed by John Larsen, of Idaho Springs. It is reported that a new and modern compressor plant will be installed at an early date, as the equipment now in use is wholly inadequate. The adit, now in 3000 ft. is to be advanced for an indefinite distance. Stopping is under way upon the Cram vein cut 2400 ft. from the portal. A body of ore is being followed that may amount to a tonnage of $100 per ton. The property is situated in the heart of Georgetown, on Saxon Mtn.—The strike made in the heading of the Scepter adit two weeks ago, is coming up to expectations, the streak having widened from 8 to 12 in. As soon as the heading has been driven 35 ft. stopping is to be started. This property, including the Sunburst and Anton recently passed over to the Stewarts-Hill Silver Co., the consideration being $150,000. A compressor plant is to be installed soon, at the Scepter workings. M. J. Riley is resident superintendent.—The Santiago, East Argon- tine, is sending out a heavier tonnage of ore than at any time during its history. On the 5th level, Nulsh & Co. are carrying a spore on a streak of smelting ore that has been over 889 per ton in gold, silver, and copper, the last named metal running as high as 15%. Allgood & Co., who are at work on the level above, are stopping on a streak of mineral that is from 18 in. to 3 ft. wide, the first class milling $45 per ton.—One of the most im- portant mining deals which has been put through this season is that of the Waldorf Metals Co., for the purchase of the Huckleberry group of five claims, West Argentine, and a 10-year lease on the Independence, Wheeling, and part of the Commonwealth mines in East Argentine, all the property of the Waldorf Co., M. Co. The purchasing company will extend the Wilcox adit an extra 450 ft., or until the Wheeling-Independence vein is cut, and thorough- ly developed the latter, as well as the Commonwealth, which has already been intersected. A cross-cut is to be

July 18, 1908.

OLMEN COUNTY.

The Hampton Con. Mines Co. is preparing plans for the installation of electric equipment and air-drills on its Hampton group of claims, in Russell gulch, near Central City.—It is reported that the Black Hills & Denver Gold Mining Co. has adjusted its financial affairs so that opera- tions can be resumed at their property in Boulder Park during the coming week. Eastern people are interested and it is expected that they will resume work in their shaft, afterward commencing work in the adit.—Denver capitalists, who are interested in the Gamble gulch property on the head of Gamble gulch, near Central City, are figuring on resuming operations within a short time and will install a plant of machinery.

LAKE COUNTY.

The Oveus M. & L. Co., on Rock hill, in the Leadville district, has resumed operations. The property comprises 15 acres belonging to the Argus Mining Co., and has a 500-ft. shaft.—Ohio men, who last fall bought an interest in the Holy Cross property, are now installing a stamp- mill on that property.

OURAY COUNTY.

The first shipment of two cars of ore from the Lund- bury lease, on the Yankee Girl, in Red Mountain, was made last week. Twenty-five card loads, valued at approximately $10,000, have been taken from the mine by these lessees since January.

SAN JUAN COUNTY.

The Black Wonder and the Sterling groups of claims, in Burrows Park, will be worked extensively this season. The Sterling is owned by F. J. Pienaar & Co., of New York, who have already started work. The Black Wonder has been purchased by English capitalists, who will make extensive improvements on the mill, including the installa- tion of some new process for treating the ore.—The shipments of crude ore from Silverton, during June, exceed that of May by 20 card loads, while the shipments of concen- trate show a decrease. The figures for June are 3100 tons of concentrate and 875 tons of crude ore.
SUMMIT COUNTY.

The new electric drills in the Arctic mine were started this week. The new mill at this mine will be ready for operation in the near future.—The Senator mill has been leased to D. B. Cox and J. E. Lawrence, of New York. The lease carries with it the right to use the Senator adit. The same men have also purchased the mining property belonging to Tobias Frielweh, on North Star Mt., and will drive a cross-cut from the Senator adit to strike the Frielweh adit. A force of 25 men will be employed.

TELLER COUNTY.

According to report, the big Union mill of the U. S. R. & R. Co., at Florence, will be put in operation again as the result of the recent decision of the management of the Golden Cycle Co. In refusing to make any more contracts to treat custom ore, the U. S. R. & R. Co. is to be the only mining company to be killed by the destruction of the Cripple Creek district, with the exception of the Golden Cycle, and in view of the fact that the production of the camp is increasing it is very probable that it will be found necessary to re-open the Union plant.—Mullen & Co., leasing on the Riggi group, on Battle Mtn., have recently installed an electric hoist and new compressor. They expect to increase the shipment of ore to three cars per week. The Isabella-side-mill has recently shipped an $12,000 gold brick, which is the clean-up from a 27-day run on the Isabella dumps. These dumps had been previously worked over twice by lessees and averaged only $3.56 per ton. The shipments of ore from the mine continue at the rate of about 45 cars per month, the ore assaying about two ounces per ton.

IDAHO.

SHOSHONE COUNTY.

(Special Correspondence.)—It has been announced that the Snowstorm Mining Co. will again join the list of dividend payers. The company has now all the Indehtedness, incurred during its period of idleness, cleared by the management and considered advisable to delay the disbursements of profits and to commence more substantial payments. It is generally believed that the divident of the company will be the same as formerly, and at the rate of 45 cents per share. More than 3,000 shares of the stock have been purchased in the New Chicago property, at Murray, and ten car-loads of the ore have been shipped by the Idaho Northern railroad for shipment as soon as the Idaho Northern railroad is completed.—The Mineral Farm property, near Molina, will drive a 1,200-ft. adit to reach its vein at a depth of about 500 ft. The portal of this adit will be less than half a mile from the Northern Pacific railroad and will run substantially parallel to the hill tunnel of the Mining and at a distance therefrom of about 1000 ft. When ready for machine drills, electric power will be used and the transmission wires will be carried from the Mining Mill, about half a mile distant from the portal. The vein on the property is over 100 ft. wide and shows a streak of five feet of heavily mineralized matter consisting of oxidized rock heavily impregnated with iron.

—Development operations on the Mastodon-Cœur d'Alene properties, near Slate and near the Idaho and Montana, Milwaukee & St. Paul railroad, will be resumed at once. The last development was through a 300-ft. cross-cut adit and the new work will be the running of a 900-ft. drift, which will give good depth on the vein. The property is a gold, silver, and lead producer. An 8-ft. drift was run for exploration purposes last year and opened up fair carbonate ore. The vein shows gold from the top and in the outcrop there is some silver ore. A large body of copper ore has been struck here, by Sisson & O'Neill. The width of the vein has not yet been ascertainment. The whole mountain is copper-silver and it is considered more than probable that a large deposit of ore exists. The mine is on the North Fork of the Cœur d'Alene river.—The annual meeting of the stockholders of the Alameda Mining & Milling Co. was held last week and 15,000 out of 1,255,000 shares of stock were voted. Stockholders were elected for the ensuing year.

A statement was read at the meeting showing the condition of the affairs of the company. So far no pay-off has been struck but the men at present are driving on straights and good indications are in sight.—The Stanley mine, at Burke, has been closed for several days and from present plans it may remain closed for some time. The reason for shutting down is said to be the fact that the lease on the mill of the New Jersey Co. has expired and has not been renewed. The Stanley is owned principally by Spokane capitalists, and produces gold and antimony.—The drifting on the property of the Rainbow Mining & Milling Co. has opened up a streak of ore giving a good content of gray copper. From 1 to 2 oz. of ore has been exposed and assays of this give returns of 46 oz. silver, and 15% copper.—A fan is being installed at the property of the Bank Traveler's mine, under Co., and it is expected that as soon as this has been completed the force of men at the property will be increased. A long adit is being driven to tap both ledges at depth. The adit has been driven more than 500 ft. since work was started last October. It is estimated that 400 ft. more of driving will reach the first lead, while the second is about 550 ft. farther on.

Wallace, July 14.

KANSAS.

CHEROKEE COUNTY.

(Special Correspondence.)—One of the most important movements in several months in the district is the reopening of the old Hartley land, at Cave Springs, by McCullagh & Murdock. The land is being drained by the installation of a pumping mill, and the drainage will be under Salters, and when the surface and the unwatering of the camp has thus become a very serious proposition. However, the new company has taken up the problem and already has drained the ground to the 80-ft. level. Work will be continued till the ground is workable to the 105-ft. level, when most of the old mines can resume operation. A new strike of imporance was made upon the Burge tract of this ground last week by Butler & Burruss, of Galena. A good body of zinc-blende was struck at 74 ft. running from 12 to 15% zinc. Four new shafts are going down in the vicinity, and many applications have been made for sub-leases.—The Herald Mining Co. has closed down for a period of 60 days to enable them to do some repair and development work. It is the plan of the company to sink the present incline, shaft 75 ft. deeper, or until it penetrates the bottom of the ore deposit. The incline shaft will then be connected by drifts to the vertical shaft and ore hoisted from each. The Hartford Mining Co., operating south of Galena, has installed new machinery to facilitate the development of the ground. A new mill has recently been completed and will soon be ready to operate. The ground is not yet fully developed, but will be thoroughly worked during the remainder of the season. An exceedingly rich strike was made north of Galena, on a lease adjoining the old Helen Hunt tract. The drill entered ore at 227 ft. after passing through limestone for some distance and at 259 ft. rich ore cuttings were still taken out. On the adjoining lease ore was entered at 225 ft. and continued to 274 ft. The dies assays very high on the ledge, and it is believed the richest ore found in the Galena camp. Both tracts will be drilled and fully developed.—Booughton Bros., operating a 40-acre lease near Galena, have installed a new pumping plant and will have the ground drained this week. A number of prospects are ready for development on this tract and a concentrating plant has been erected by the original lessors.—Shelach & McKinney, after a long shut-down, have re-opened their property and started the mill. During the shut-down a large amount of development work was
accomplished.—The Old Abe and Myrtle mines, which were closed down some time on account of the scarcity of work and low ore price, have now resumed operation.—The Omaha plant, milling the ore from the Hobo mine, which, with the ore from the south shaft of the Omaha, keeps the mill running to full capacity. The Omaha has started the sinking of a third shaft on its lease.

Galena, July 13.

MISSOURI.

JASPER COUNTY.

(Special Correspondence).—Although the past few weeks has noted the closing down of a number of important properties because of the low price of zinc ore, still there have been a considerable number overhauled and put in operation. The Old Conqueror mine, in the Carthage, has been made a new sinking elevator and after making other needed repairs on the plant, resumed operation. The ore is now taken from the southeast shaft near the Jack Rose line, where the dirt is exceedingly rich. McNeal and associates on the Jack Rose ground are developing the same run of ore and have cut an air-drift up into the Old Conqueror’s drifts, thus furnishing ventilation to both mines. In the Tussing camp, a new ground, a ducer, re-enters the producing list after a long shut-down. The ground was drained a few weeks ago by a small pump. A 150-ton mill, on the property, is sufficient to handle the dirt. The ore is high grade, running from 4 to 5% zinc concentrate.—The Garnet mill, south of Carterville, is to be overhauled and put in operation as soon as possible. This property was closed down last year on account of a disastrous cave-in, but work was started on the ground this year. The ore was treated at the Fullerton mill, until the plant burned a few weeks ago. The mill upon the Garnet ground will now be repaired and made ready for the treatment of the ore.—A rich strike was made upon the Roach ground, west of Joplin, recently purchased by Roach, Roachley & Glover. The deposit was opened at 100 ft. and consists of a 25 ft. face of ore, running from 10 to 15% zinc-blende. The ore occurs in spur ground, and the dirt hoisted is full of calcite crystals. The underground development will be hastened and the ore will for the present be cleaned upon hand-jigs.—In the Diengue camp the Wolffsheath Mining Co., of Chicago, has opened up a rich deposit in the shaft at 232 to 241 ft. The ore is largely zinc-blende, though a small percentage of galena occurred. The Lincoln Hills and Arrows Beauty No. 2, the company plans to erect a mill as soon as underground development is well under way.—A rich strike of zinc-blende was made upon the Reliance tract, south of Webb City, upon what was formerly called the Baker tract. One corner of the lease was very productive in the early days, but the remainder of the land was of doubtful value until the recent strike made in five drill holes. A shaft has been sunk which fully verifies the drill record.—A new deposit of galena and zinc-blende was opened this week, in Elm Hollow, by William Pierce and associates. An old lease was taken over and drilling begun which resulted in the discovery of a rich ore deposit at 112 ft. The shaft proved the ore to be richer than the drill showed. Driving has been done and a fine set of ore holes were drilled last winter entered ore at 35 ft. and the drill remained in ore to 196 ft. The drill cuttings were among the richest ever taken from a mine in this district.—A deal was recently closed whereby Tobias & Eastwood, of Carthage, purchased a half interest in a lease of 10 acres of mining ground, north of Knight’s station. The land is well developed mineral land upon which are three shafts in rich ore, and the whole tract is well proven by the drill records.—The Quick Seven Mining Co., of Alba, holding first lease on an 80-acre tract, suspended all but 12 acres of the tract for mining purposes. Mining men from all over the district were present and the leases were quickly disposed of. This tract was recently drilled and very rich ore found near the surface than had hitherto been found in the Alba camp. Shafts are now being sunk and development hastened preparatory to the erection of a mill. Eight or more drills are now under ground and prospecting work progresses steadily.—Several new mines have been completed or in course of erection which will soon be in the list of operators. The Brazos mill, north of Webb City, has been completed some little time, but owing to the necessary delays was started only a few days ago. The plant is of 300 tons capacity and will operate upon ore from the 170 ft. level—the common depth of the sheet ore in this part of the field. The ore is high-grade and will mill over 4%. The ground is not yet fully developed, but two shafts are into the ore body.—The Endeavor Mining Co. has secured a lease upon the old Prudential tract, at Prosperity. The mill was burned some months ago, and a mill of 250 tons capacity is now being erected by the new company. The property adjoins the Giff. There lease, which was sold for its richness. The ground is well developed. One shaft is now down 215 ft. and a second shaft is being sunk near the mill. Ore is being taken from both shafts.

Joplin, July 13.

NEVADA.

ELKO COUNTY.

The new mill of the Gold Crown Mining Co., at Gold Circle, will be in operation in about 60 days. It will be of fairly water-proof construction and is considered the finest mill in Nevada. It will be situated at the foot of East street.—A recent strike on the Golden Chariot property has created considerable excitement and mine leases have started work. It is claimed that an 8 ft. vein will assay $350.—Considerable excitement is prevalent at Cobre, the junction of the Nevada Northern and the Southern Pacific, owing to the discovery of high-grade silver and copper ore about 12 miles east of there, in the Lory mining district. A vein 10 ft. wide, carrying 17% copper and 300 oz. silver, was uncovered a week ago by Kollough & Lang on the Lillian group, at a depth of 25 feet.

EMERALD COUNTY.

A strike of $3400 ore is reported at the Miss Jessie claim on the Laguna ground. The shaft will be sunk an additional 100 ft. and a cross-cut run toward the vein. —Work is to start at once on the Gold Button, in the eastern part of the Goldfield district. It is the property of Chas. F. Potter, and over $10,000 has already been spent in development.—An extension to August 1, 1909, has been granted the Liverpool Goldfield Co., by the Goldfield Consolidated Mines Co. The leasehold is on block No. 2 of the Golconda claim. At present the shaft is 400 ft. deep and is being sent down as possible. No lateral work has been done and none will be attempted until pay-ore is struck.—A station is being cut for the second level in the Gotwaldt Combination M. & L Co’s shaft. The sill level is 305 ft. from the surface. A cross-cut will be run for the eastern section, to be followed by a second block and the shaft will be sent to 500 ft. as rapidly as men and money can do the work. Meanwhile cross-cutting is in progress on the 255 ft. level, which is in solid quartz. The lease has been extended by the Goldfield Cons. Mines Co. to September 1, 1909.—The Goldfield Cons. Mines Co. has given R. W. Norrington an 18-months’ lease on the south 400 ft. of the Grizzly Bear claim. Work has been started and an electric hoist installed. The operations are financed by the newly organized Consolidated Jumbo Mining & Leasing Co., which has $50,000 cash in its treasury.—The mines of Goldfield produced during the week ending July 10, a total of 2162 tons, the estimated value of which is $163,700. During the same period the Tonopah mines produced 4775 tons of an estimated value of $119,375.
EUREKA COUNTY.

The Cortez mine, at Cortez, 35 miles south of Bovawave, has been recently acquired by the Cortez Metal Recovery Co., of which A. W. Geiger and Eugene Hewlett are the moving spirits. The new company is now erecting a 100-ton cyanide plant to treat the old tailing from the hypo-hydration plant, and will also open up and operate the old mine. A shipment of silver precipitate, cleaned up from the old mill, was recently made which netted $6000. Apparently the old camp of Cortez is on the eve of a season of renewed activity, and other well-known mines may be worked again.

HUMIDELT COUNTY.

The Green-Haynes lease made a shipment of 30 tons of ore last week, from its holding on the Mazona Hills ground at Seven Troughs. It is claimed that 60 sacks of the shipment will mill as high as $2500 per ton. The hoist of the Prior-Chadbourne lease, the control of which was recently bought by Minneapolis capitalists, arrived on the ground yesterday and will be immediately installed. This lease adjoins the Green-Haynes lease on the north and contains the same vein system. The first shipment from the Whihuja lease, at Seven Troughs, went out last week. Several sacks of picture rock were sent by automobile to Lovelock to be converted into bullion. It is safe to say the ore is worth 200 pounds and will net the company between $10,000 and $15,000. Some of the most beautiful specimens ever taken from this camp accompanied this shipment. The Salt Lake Development Co., composed of a number of Salt Lake mining men, owning and operating the Santa Reta group at Farrel, in the north end of the Seven Troughs district, has taken up its option on the Yellow Metal claim, adjoining the Santa Reta. An excellent strike has already been made on this claim and the company will now thoroughly develop it.

The Kindergarten Mining Co. has holdings that cover the series of parallel veins on the principal zone, but on the south side of the Seven Troughs canyon. Two veins have been opened by adit levels, from which winzes have been sunk on the ore. A new working shaft has been started higher up on the side-hill, where a gasoline hoist will be installed. The Kindergarten 10-stamp mill is being operated on ore from one of the veins referred to. The ore previously shipped ran $400 per ton, and the mill is running on ore that carries $120 per ton. The low-grade ore runs as low as $10 per ton, and this is to be mixed with the higher grade for treatment. L. A. Friedman is president of the company and C. H. Ellithorpe is manager. The Bellows Troughs Mining Co. is 2000 ft. south of the Kindergarten, on the same belt. Friedman and Ellithorpe are also in control of this property. A vertical shaft has been sunk over 500 ft. and the purpose is to continue sinking to 1000 ft. The vein here has a width of 6 to 10 ft. and it has yielded some of the highest-grade ore in the district.

The Seven Troughs Signal Peak Mining Co. has a property lying between the Kindergarten and the Fairview. It is owned by the Salt Lake people, and is in charge of Frank McIntire. They have 570 ft. of tunnel-work, and a 65-ft. shaft. It is said that 145 ft. of this work is in ore that runs $55 per ton.

LAURDER COUNTY.

The Austin Manhattan Con. Mining Co. will soon begin operations upon an extensive scale at Austin. This company recently acquired 87 patented claims which included nearly all the old-time producers of the district. The enterprise is backed by a strong Eastern syndicate.

LINCOLN COUNTY.

The grading for the new smelter, at Nelson in Eldorado canyon, is completed and the work on the buildings is being rushed. The plant will have a capacity of 50 tons and is the first gas smelter to be erected in Nevada. The equipment includes two 50-hp. and one 10-hp. gas engines, three compressors, one 50-ton Loder furnace, gas generators, high-pressure pumps, and minor accessories. The plant will treat ores of the Searchlight-Santa Barbara Co., and will also accept custom work. The Red Cliff property, comprising nine claims, and lying a short distance northeast of Searchlight, has been sold to E. L. Pollock and others, of Chicago. The first car of ore, 662 sacks, from the leases of the Double Standard, at Crescent, was hauled to the railroad and shipped from Nipton to Utah smelters last week. It represented the combined output of the Red Star Mines Co., Davis & Russell, and Parsick & Jones for the week. The new smelter-plant at the Day mine, at Jack Rabbit, is nearly completed, and will be in operation within a week.

NEVADA COUNTY.

The MacNamara mine is keeping up its heavy shipments of ore, three cars of over 50 tons each having been sent to the Belmont mill at Millers this week. This ore is of very good milling grade, averaging from $45 to $50 per ton.

The Madigan lease at Round Mtn. has been acquired by the Solid Gold M. & L. Co., of which C. E. Johnson is general manager. A Merrill mill has arrived and will be installed at once. The Round Mountain Antelope Leasing Co. has recently uncovered two feet of rich ore which was found at a depth of 50 ft. Arrangements have been made to treat the Antelope ores in the new Dalsy mill when it is completed.

WASHOE COUNTY.

It is announced that the new Selby mill, at Jumbo, will be completed and in operation by August 1. The timber has all been framed and the concrete foundations are now being put in. The ore from the Barco will be the first to be run through the mill. The shaft on the Syene, at Jumbo, has been cleaned out to a depth of 90 ft. and sinking has been resumed. The management expects to sink to a depth of 150 feet.

BRITISH COLUMBIA.

The ore shipments from the Granby mines for the month of June were $5,257 tons. The shipments for the first six months of 1906 total 278,574 tons, as compared with 278,582 tons during the same months last year, a decrease of 100,900 tons. A number of improvements to its local mines are now being planned by the Dominion Copper Co., among which will be an aerial tram line from the Idaho to the Stemwinder. Hereafterore the ore has been shipped from the Idaho over the Great Northern railway to near Denver, where it was transferred to the C. P. R. for shipment to the company’s smelter at Boundary Falls. By shipping direct by way of C. P. R. a saving of 15 cents per ton can be effected. The Evening Star, at Rossland, has uncovered a new 4 ft. vein that assays about $35 per ton in gold. The Bullion mine, at Odlia, resumed operations last week after a shut-down of two years. What is thought to be the most valuable carload of ore yet sent from the south belt at Rossland, has been shipped by E. Wolfe & Son from the Mayflower mine. It is galena ore and is said to be worth $1200. The ore was carefully sacked so as to bring it up to as high a grade as possible.

A fire last Friday, at Grand Forks, destroyed one-half the business district, entailing a property loss of $250,000 and the killing of one man. The Hewitt Mining Co. has been organized and certificate of incorporation granted. The head office of the concern will be situated in Wilmingtton, Delaware, and the local office at Nelson. The company will operate the Hewitt and other properties near Silverton.

MEXICO.

The St. Sofia mine, St. Catalonia, Oax., will erect a 20-stamp mill. The Huastea Petroleum Co. has been given a concession to export oil and gas in the northern part of Vera Cruz. Harold Walker is the representative of the company which undertakes to expend $500,000 in exploration, pipe lines, and the like. Plans are made for a 20-stamp mill and cyanide plant for El Favor mine, Hostotipilco, Jel. W. R. Ramsdell, Guadalajara, is the president of the company and will be in charge of the negotiations for the new plant.
Special Correspondence.

LONDON.

Tywarnhaile Copper Mine.—Boscawell Flotation.—Mond Nickel Co.—Brimsdown Lead Co.—Snowshoe Gold & Copper Mines, Ltd.

In your issue of May 30, I gave some information about the closing down of the Tywarnhaile copper mine in Cornwall. I have since been informed that one of my statements was incorrect, namely, that the suspension of operations was advised by Mr. W. Fischer Wilkinson. The fact is that I drew an incorrect conclusion from the information in my possession. It is true that Mr. Wilkinson several times examined the property on behalf of the Consolidated Gold Fields of South Africa, which Company had supplied the working capital, and it is true that the Consolidated Gold Fields decided to stop work. But I was wrong in drawing the conclusion that Mr. Wilkinson advised the Company to take this step. Personally, I owe Mr. Wilkinson an apology for placing a wrong construction on the information he had given me. To properly explain the circumstances I ought to mention that the mine was re-opened by the firm of Bainbridge, Seymour & Co., at the time when the original Elmore oil concentration-process was invented, and the chief shareholders in the Company formed were Mr. Emmon Bainbridge, Professor Cox, Mr. R. A. Varden, and Mr. Stanley. For this reason I can only give the official explanation that considerable money was required to unwater the mine and properly open it up, the firm approached Mr. Wilkinson, who formerly was professionally connected with them, and who was at the time in the service of the Consolidated Gold Fields. In this way the Gold Fields became interested in the Tywarnhaile Co. and put up what was supposed to be the necessary additional capital. As regards my objection to the mine being closed down, I can only give the official explanation that the Gold Fields considered that the funds in hand were not sufficient and that they did not see their way at that time to provide any more. This is what Poo-Bah would call a "bald and unconvincing narrative," but under the circumstances we will let it go at that.

While writing of blunder matters, I should like to mention that in the issue of the Boscawell mines referred to by me last week has proved a failure. A certain amount of money was subscribed, but in the opinion of Mr. A. K. Barnett, of Penzance, and Mr. J. H. Collins, two of the directors, the amount was not sufficient for the purpose. So it has been necessary to return the subscriptions. It is a great pity, and I am sorry for Mr. Steuart, who must have dropped something like £10,000 in this abortive proposition.

A few weeks ago in writing of the firm of Brunner, Mond & Co., the chemical manufacturers of Northwich, Cheshire, I mentioned that some of the processes of a more speculative nature taken up by the firm were placed under separate organizations and operated independently. I instanced the Mond Nickel Co. and the Brimsdown Lead Co. The yearly reports of these two companies have now made their appearance so it is opportune to give some information about them. The Mond Nickel Co. has had a remarkably successful career during the last three or four years, and its prosperity is still advancing rapidly. The Company was originally formed in 1890, after Dr. Mond had experimentally conducted his new process for something like eight years, during which its commercial adaptability hung in the balance. At first the Company suffered reverses owing to the danger to life and health from the carbon monoxide and other fumes given off, but when once these troubles were overcome, the success of the Company was assured. As is well known, the Company produces a copper-nickel matte at its mines in the Sudbury district, Ontario; after refining the matte at Clydach near Swansea. The capital is £200,000 divided into £250,000 of 7% cumulative preference shares, £300,000 of ordinary shares, and £50,000 of deferred shares. After 7% has been paid each year on the ordinary shares, the remaining profit is equally divided between the ordinary and the deferred shares. The ordinary shares received their first distribution in 1905 when 6% was paid. In succeeding years this rate has risen to 10 and then to 15%. The deferred shares have received dividends of 18, 33, and 45% during the last three years. The demand for the Company's products, metallic nickel and copper sulphate, continues to increase, and the mine at Garston about 30 miles distant from the Victoria mines in Ontario, has had to be opened up and equipped. In order to provide more power, a plant for the generation of electric current is being erected on the Vermilion river, and it is expected that the Victoria mine and the smaller well be equipped with electric power by the end of the present year. In order to provide the necessary capital, and also to extinguish the loan-account created in the early days while the fumes-difficulty suspended the operations of the plant, the directors are intending to issue £250,000 new preference shares, for which a ready market can be obtained.

The other subsidiary of Brunner, Mond & Co., the Brimsdown Lead Co., has been uniformly unfortunate and at the present time it looks as if the works would have to be closed. The operations consist in the application of the Bischof process for making white lead. It is one of the rapid methods of corroding lead by acetic acid, and its chief point of advantage lies in the fact that it produces a uniform oxide instead of a mixture of different oxides. I do not think that any advantage is claimed for the white lead produced except that the process occupies so much less time than the old Dutch method, and consequently has less metal locked up. On the other hand the process is of such a nature that the plant must work continually, and at full capacity. Consequently in dull times, metal gets locked up in unsold stock. I believe that the real cause of the failure is the indifference on the part of the users of white lead. The qualities of certain old established brands are known so exactly by decorators and painters that unless a considerable advantage is offered in the way of reduction in price there is not sufficient inducement to try a new make. It is possible that, if the white lead had been introduced as the Brunner-Mond instead of the Brimsdown brand, it might have come forward more readily. To be directly connected by name with a firm known for the quality of its chemicals is a large part of the battle. But I may be wrong in making this reflection, and there may have been good reasons why the greater name should not have been adopted. It is noteworthy, too, that there is not a Brunner or a Mond on the Board of Directors, though there are plenty of them in the Board. Though though equalizing in every way possible, continues to incur losses every year, and unless some heroic policy can be discovered, the end will have to come before long.

The Snowshoe Gold & Copper Mines, Ltd., owning the mines of that name in Boundary district, British Columbia, reports that it made a profit on operations during the financial year ending September 30 last, and that the debit balance of stock is accumulated to a considerable amount. The mines are not being worked, owing to the low price of copper. Your readers will probably be familiar with the history of this Company, and will remember its flotation in 1901 by Mr. A. J. Macmillan. Though the ore deposits are extensive the contents are low, and the Company never paid a dividend. More recently the mine has been leased to the Consolidated Mining & Smelting Co. of Canada, and work is resumed whenever the labor supply and price of coal, and smelting price of copper, have been favorable. During the year ended September 30 last, the mine was worked by the lessees for about two-thirds of the time, the period of idleness being the winter of 1906-7, when the strike, the scarcity of coke, and imperfect transport facilities, suspended operations generally throughout the southern part of British Columbia. Altogether 93,017 dry tons of 3000 lb. were shipped by the lessees during the period under review, containing approximately 1.2 dwt. gold, 0.3 oz. sil-
The returns for May show that this was a most satisfactory month for the mining industry. The total output for the Transvaal was declared to be $51,992 oz., valued at £2,472,143. An enumeration of the results of the month's operation was the increased profits earned by the mines, due to strenuous efforts being made by the mines to get the very best results. The Rand's contribution to the May output was 558,243 oz., valued at £2,571,265, while the outside districts produced 23,749 oz., valued at £100,578. During May there were 8929 stamps at work in the Transvaal, of which 8475 were in the Rand. The largest number of stamps on the Rand was the Simmer & Jack mine, whose large battery of 250 stamps and four tube-mills produced 26,551 oz. fine gold. Second on the list was the Robinson mine, with 26,190 oz. fine gold. Third was the Robinson Deep with an output of 20,646 oz. There were fifteen companies that produced during May 12,500 oz. or over.

During May there has been quite a stir among the idle mines of the Rand, there is strong talk of a number of them starting up very soon. The Bantjes mine, which has been idle since 1897, will no doubt become a producer in another year. The Aurora West mine is making preparations to begin crushing operations once more. Then, too, that huge deep-level proposition, the Simmer Deep, will start crushing for the first time by the end of the year. Taken altogether, the industrial development for the month of May is one of solid advance.

The fine showing being made by the mines of the Rand is attracting the attention of investors in Europe, and the share-market has been quite animated during the past few weeks. There is a distinct improvement among them all, and one or two of the leading shares have advanced very rapidly. Take Modderfontein, for instance: early in May the share price of this mine stood at $1.15, each, while today they are readily bought at $3.88. There is every reason for the advance, for the mines have made great progress recently, and is now looked upon as one of the great gold mines of the world. Its future seems assured, and as there is a huge claim area, its life will be a long one.

The returning prosperity among the gold mines does not seem to affect the diamond mines, which are in a bad way. Things about the mines at Kimberley seem very depressed, after the lively days of the past. How this crisis in the diamond market will end, it is hard to say. While the severe financial depression all over the world has much to do with the trouble, it seems that the principal difficulty is the war between the Kimberley mines and the Premier (Transvaal) Diamond mine. If the market is swamped with diamonds, these jewels will be looked upon as marbles by fashionable people, and will not be much more valuable. If there is one business in the world that justifies the strictest monopoly, it is the diamond business. Cedi Rhodes saw this point very clearly years ago, but unfortunately South Africa has no such man now to direct her.

Of course mining people on the Rand are thankful for the better feeling existing here, but some of the more thoughtful are asking whether the improvement is permanent, or only a spurt? In the market. The labor difficulty causes much apprehension for the future. It is true that there is ample Kaffir labor for present requirements, but if a number more gold mines should start up, and there should be anything like an industrial awakening in South Africa, the demand for labor will be so much greater than the supply that we will be face to face with a serious shortage and business would receive a serious set-back.

Much interest is being shown in the Randfontein mines in the western part of the Rand. These shares are now very popular. About three months ago they were quoted at 20s., while today they stand at 3.1. There are vast potentialities at Randfontein. Besides the mines already at work, two huge mills of 300 stamps with tube-mills, are to be erected in the future. At the Randfontein Central mine, when the crushing operations are complete we expect to get through 30,000 tons per month and make a profit of about 10s. per ton. Further south the idea is to put up another 300-stamp plant. One is tempted to ask, why not put these plants together and make one of 600 stamps? The mistake of the past has been the small separate reduction plants. Centralization of plants is the best policy for the future.

MEXICO.

Competition in Oil Business.—Oil Development on Isthmus of Tehuantepec.—Smelter at Chihuahua.

Early in February it was rumored in Mexico that we were on the eve of a battle royal for control of the oil market of the Republic between S. Pearson & Son and the Waters-Pierce Oil Co. The Waters-Pierce Oil Co. is a branch of the Standard Oil Co. that has had absolute control of the oil business in Mexico for more than a generation. The firm of S. Pearson & Son was the contractor and builder of the Tehuantepec National railroad. At a number of points on the Isthmus of Tehuantepec excellent oil was found by S. Pearson & Son, and the company has been developing the field, and it is now being used by the Tehuantepec National railroad as fuel. The flow from the wells, however, was far in excess of the needs of the railroad, and that it might have a more general commercial value S. Pearson & Son started last year at Minatitlan an immense refinery. This has recently been completed. It has a capacity of 5000 bbl. per day, and as soon as the necessary tanks have been erected with a combined capacity of several hundred thousand gallons. A pipe-line 15 miles long was put in from San Cristóbal, the main oilfield, to Minatitlan, and thence a railroad to kilometre 30 of the Tehuantepec National, giving access to the wharves at Coatzacoalcos. From this point the Company's lighters could convey the oil to any port along the coast, and additional lines can be made to the shares of other oil companies, with a branch line to Vera Cruz to supply the Mexico City market and other territory tributary to Vera Cruz. All this was to be completed, and the break in the market was scheduled to occur in March or April, but those months passed without a ripple. Then in May it was reported that S. Pearson & Son had sold out to the Standard Oil Co. for $5,000,000.

The amount seems reasonable for the Pearson holdings in the States of Chiapas, Campeche, Tabasco, Vera Cruz, San Luis Potosi, and Tamaulipas, on which are held the rights for the exploration of petroleum for 50 years from 1906 under a concession from the Federal Government. By the terms of the contract 7% of the value of the output goes to the Federal Government and 3% to the State in which the oil is produced. But Pearson's relations with the Mexican Government are such that a sale to the Standard Oil Co. did not seem feasible, so it was given out that
a merger had been effected between S. Pearson & Bon and Furber (of the Old Fields of Mexico) and Dohenev (representing the Mexican Petroleum Co.), the two largest companies in the San Luis Potosi, Vera Cruz, and Tamaulipas fields. Now, however, it is stated on good authority that S. Pearson & Bon has shipped from the Minatitlan refinery three carloads of gasoline and petroleum to Mexico City, and that immediately on its arrival it will be placed on the market at a reduction of 20% from the prevailing prices. The same tactics will be pursued at other points in the Republic. If this is done an oil war will be precipitated at once. It would be a blessing to consumers who have been bled by the Waters-Fierce Co. long enough.

In Chihuahua it is definitely stated that the new plant of the American Smelting & Refining Co., situated on the Rancho de Avalos, six miles southeast of the city, which was completed last December but not blown in, will be started up soon after July 15. The roasters have been in operation for three weeks. On June 10 the company began the shipment of ores from its mines in Santa Eulalia to the Chihuahua plant. These were followed by ores from Sierra Mojada and Parral. Then, to relieve the Torreon Metallurgy Co. from the embarrassment consequent upon last year's drop in metal prices and its large stock of ore on hand, that company's ore from Naco, San Francisco del Oro, and other points, has also been treated there and there appears to be some of the Chihuahua plant between 400 and 500 tons per day. At least two furnaces will be blown in. This diversion of the ores to the Chihuahua plant has caused a large decrease in the receipts from Mexico at the El Paso smelting works. The latter plant may have to reduce the tonnage smelted, if there is not an early rise in the price of lead and silver.

JOPLIN, MISSOURI.

Decrease in Production.—Activity at Chitwood and Leadville Hollow.

—Discoveries on New Geological Horizon at Cave Springs.

The recent recession in the smelter market, and the consequent collapse of the hopes of many of the zinc-ore producers who had been counting on an advance, has caused discouragement to settle upon the district. The result has been to enlarge the ranks of idle properties. In the Oronogo district, which produces normally in excess of 255 tons per week, only one plant is in operation. This will depress the output below 50 tons per week. In the Webb City camp a large number of drills have been forced to close down indefinitely. The Little Princess, which has been producing steadily throughout the period of low prices, has over 2500 tons of zinc-blende concentrate awaiting a market upon a $40 base. The Aylor properties are likewise piling up a large amount of zinc concentrate, estimated to be in excess of 1800 tons. Outside of these big piles there are any number of smaller plants in the district, as the few other plants that are running have their ore sold every week to the ore-buyers, who readily take what is available at or below $35.

Despite the gloomy outlook for the district a large amount of underground development is still in progress. Many of the companies shutting down their plants continue to employ a portion of their men in development work. New shafts are being sunk, and new prospect drills are being driven, and other work incidental to the development of new reserves. The camps in which the greatest amount of work is in progress are the so-called soft-ground camps, where the ore hoisted carries a high per cent of concentrate. South and southwest of Joplin a large amount of such development is in progress. On the Johnson and Buttes lands five new companies are opening mines at which as many concentrating plants will be erected. In every case the orebody developed was about 100 ft. deep. The ore mined is of the variety called "free-milling" in this district. Joining these three companies is completing the development of a portion of the Reising land upon which a new 'sheet-ground' deposit was discovered about eight months ago.

Northwest of Joplin there has been considerable activity in the old camp of Chitwood and in Leadville Hollow. The Lounetta and Barnard companies have drilled and developed two very rich deposits of zinc-blende. The first has brought its property to the producing stage, having completed the erection of a small plant which has begun operation. The latter company is yet developing its lease. In the same vicinity the Hermit Mining Co. has opened what appears to be the richest deposit of free zinc-blende yet developed in the Leadville Hollow camp. At a depth of 60 ft. a recent working ran into ore containing from 20 to 30% zinc-blende. The most important development attempt has been in the Cave Springs camp, and north of Galena. What appears to be an entirely new ore-horizon is being opened. The ore lies deeper than elsewhere in the district. In all the holes so far drilled, and in the shafts opened, the ore is found between the 222 and 300-ft. levels. The drill-records show this deposit to be far below the horizon of the Grand Falls chert in which the greater number of the ore deposits of the district occur. As far as known no workable deposits of galena or zinc-blende have hitherto been opened or even seriously considered below the Grand Falls chert. This discovery therefore apparently marks the beginning of an epoch of working deeper orebodies. The deposit is of abnormal thickness, running from 55 to 76 ft., and the ore is imbedded in a soft matrix of dolomite and small amounts of chert. The quantity of concentrate from the ore ran high, usually from 4 to 20%. The Herald Mining Co. finally sunk a shaft and upon opening the deposit fully verified the drill-records.

Just north of Empire City and Galena, Robertson & Ping have been drilling on the old Helen Hunt lease. The drill-cutterings showed the same formation at practically the same depth, catching the ore at 222 ft. and maintaining the same depth as at Cave Springs, namely, 300 ft. The ore came far below the Grand Falls chert, and was in the same soft dolomitic limestone. These deposits are in a class by themselves, and will require a revision of theories as to the genesis of the lead and zinc deposits of this field.

BUTTE, MONTANA.

Reins Copper Co.—North Butte Co.—Changes in East Butte Mining Co.—Davis-Daly Estates.—New Installation by Pittsmon Copper Company.

The directors of the Reins Copper Co. have adopted a resolution which will be submitted to the stockholders at their annual meeting at Butte, August 12, providing for the issuance of $600,000 in first mortgages, 6% gold bonds, maturing in five years from the date of issue, with interest payable semi-annually. The mortgage will cover all the property of the Company in the Butte district, and the bonds are to be issued to pay off the present indebtedness of the Company and provide funds for its future operations. The directors are: J. M. Guffey, E. W. Marland, W. F. DeArmit, A. P. Childs, Jr., T. N. Barnsdall, George D. Prentice, and W. F. Johnson, all of Pittsburg. The Reins Copper Co. owns the Combination and several other mining claims on the east side of Anaconda hill, in Meaderville, and Colonel Guffey and his Pittsburg associates have put up a million dollars or more to purchase and develop the property. The mine was not paying when the financial panic struck Pittsburg, and operations in Butte had to be suspended. An accumulation of debts remained unpaid and numerous attachments were placed on the property.

The North Butte Mining Co. is again mining to the full capacity of its shafts, and is also engaged in cutting new stopes and stations at the 2000 and 2500-ft. levels. The first vein north of the shaft will be opened by the station at the 2200, and driving will be done on it as soon as the station is completed. At the 2000-ft. level the vein is about 100 ft. north of the station, and will not be reached by cross-cutting until about a month later. There is no reason to believe that the veins at the 2000 and 2500-ft.
levels will be any smaller or less rich than they are on the 1800, where the principal mining is now being done by the North Butte. Four hundred feet of new stoping ground will be opened by the two new levels, in a comparatively short time.

The main office of the East Butte Mining Co. has been changed from Butte to Boston, in accordance with action taken by the stockholders at the annual meeting on July 8. William P. Evertis, Robert H. Cross, and Frank P. Son, of Boston, were elected directors to succeed James A. Talbott and Patrick Wall, of Butte, and the late Henry Mueller. The other directors are Frank M. Sullivan and Charles R. Leonard, of Butte. Mr. Sullivan will also retire as president and will be succeeded by a Boston man. Patrick Wall, general manager of operations since the organization of the Company, has announced his intention to retire from that position as soon as someone else is appointed to the place. Mr. Wall has many other mining interests in Montana and Idaho which claim his attention. The change in the directorate and transfer of the office of the Company is said to indicate that William A. Palme and associates in Boston have secured control of the East Butte Co. They acquired a lot of private stock and also a large block of treasury stock, for which the East Butte treasury received $150,000. In addition to the cash the Company has 60,000 shares of stock remaining in the treasury. The East Butte has a big mine in condition for production, and owns the mineral rights under about 100 additional acres of ground, together with ground for a mill-site and for mining operations, in addition to a large copper precipitating plant.

The Davis-Daly Estates Copper Co. is endeavoring to raise money. About $180,000 was due July 1 on some of the claims, chiefly to the Daly estate, but extensions were secured from the latter. The managers of the estate had no desire to embarrass the Company and would not declare the options forfeited. The Davis-Daly Co. is still working a few men in the Colorado mine, where the shaft is being sunk 280 ft. deeper, from the 1860-ft. level. Prospecting is progressing on the 1860-ft. level, and several good veins have been opened, but they do not contain ore that would return a profit at the present price of copper. Leases working on some of the Company's claims have stopped. The Hoy lessees on the Lizzie claim quit of their own accord because they could not make money at present copper prices and pay a royalty of 25% in addition. The Hoy lessees developed two fine veins in the Lizzie ground, one vein 20 ft. wide, containing only second-class ore, and another about 3 ft. wide, containing mostly first-class ore. The veins have been developed to a depth of 290 ft. only. The Lizzie is one of the claims purchased from the Daly estate, and on which a large payment is still due.

Because the mill and lumber-men employed by the Montana Copper Co. at Hamilton, Montana, refused to accept a slight reduction in wages the saw-mill at that place has been closed. The Company desired to restore the wages that prevailed before the last raise was granted, a few months before the financial panic. The reduction proposed was 5 to 16c. per day. The employees at the other mills of the Company accepted the reduction and work there continues.

The Pittsamont Copper Co., called a holding company for the Pittsburg & Montana Copper Co., has been organized to finance the latter Company and pay off the almost overwhelming liabilities with which the Company was loaded down during the Baggagey management. The Company owns its own smelter, and during all the panic and shutdown of other mines the Pittsburg & Montana continued mining and production on a small scale, mining only ore that assayed about 7% copper. The Company has just enlarged its smelter-capacity by the installation of a new 250-ton blast-furnace. The old 150-ton furnace will be taken out and another 250-ton furnace put in its place, thus increasing the capacity of the plant to 500 tons per day. A new stand of converters is also being added, and the converter-building is being enlarged and remodeled. A new concentrating mill of 250 tons capacity is being erected, and will be in operation in about two months. Under the management of Oscar Rob, who has been in charge of the Company since the retirement of Ralph Baggagey, the property of the Company has been improved and systematically developed. The main shaft of the mine is down 1200 ft., and a winze 300 ft. deep has been sunk from the lowest level. There are eight miles of workings and a large amount of good ore has been blocked out. Some of the stopes are 8 ft. wide and full of 7% ore. The present daily output is from 100 to 150 tons, and that will be increased to meet the capacity of the new furnace which will treat 500 tons of ore per day. The Company is capitalized for $30,000,000 in shares of $100 each. It owns about 260 acres of mineral ground on the east side of the Butte district, and about 111 acres elsewhere in Montana, situated at Helena, Elkhorn, and in the Greenhorn mining district.
SALT LAKE, UTAH.
Blowing-in of Tintic Smelter.—Dividends Payable.—Bingham & Garfield Railroad Co., Organized.—Godiva Mines.—Tintic and Park Out-pit.

The date fixed for the blowing-in of the new smelter in the Tintic mining district, which has been built by the Tintic Smelting Co., has been fixed for July 24. Only the lead furnaces, however, will go into commission at that time, as the copper end of the plant is not yet ready. The forthcoming event is regarded as auspicious by Tintic mine owners, for the reason that they have been supplied with an independent market for their ores, it being no longer necessary to depend on the two larger smelting concerns for smelting facilities. While the Tintic plant was originally planned to reduce ores coming only from the mines controlled by its builders, the policy of the American and United States Smelting companies in making treatment charges encouraged the promoters of the Tintic plant to engage actively in the custom smelting business, and no less than $250,000 has already been expended in construction. Ores are now being received and the sampling mill is in operation. Dividends payable in July have been posted by the following Utah companies: Bullion Beck, 10c., $10,000; May Day, 1½c., $15,000; Utah Mino, 3c., $30,000; Utah Consolidated, 5c., $150,000. Articles of incorporation of the Bingham & Garfield Railroad Co., have been filed with the proper authorities, the corporation being subsidiary to the Utah Copper Co. While the document indicates that a line 35 miles long, and situated in Salt Lake and Tooele counties, is to be built, that is not taken as an indication that it will be completed in the near future. It is the purpose of the Utah Copper Co. to segregate the railroad from the mining and milling end of the enterprise. The company owns and has equipped approximately 10 miles of standard-gauge track, which will be turned over to the Bingham & Garfield Co. This trackage is in Bingham. It is not expected that the transportation contract of the Utah Copper Co. with the Rio Grande railroad will be abrogated because of the organization of the new company. A controlling interest in the Bingham-Buffie mine in Bingham, has passed to Nicholas Troatr and associates, who will undertake its further development. The consideration is $45,000. Last week's ore and bullion settlements aggregated $432,900, and the stocks sold on the floor of the Salt Lake Stock & Mining Exchange had an aggregate valuation of $506,000. Ore shipments from the Tintic district last week amounted to 74 carloads, the contributing mines being: Black Jack, $36,848; Eureka, 31; Colorado, 4; Eureka Hill, 14; May Day, 8; Uncle Sam Consolidated, 8; Utah Consolidated, 3; Yankee Consolidated, 5. Tintic, next to Bingham, is the most active mining district in the State. With the starting of the new smelter there, the output of the mines will be materially increased. The re-organization of the Godiva Mining Co., and the resumption of development there this week, means that this once noted producer will shortly rank as a regular shipper again. The shaft, down 900 ft., is to be continued to 1300 ft. In the Gemini mine two electric pumps have been recently installed and greater depth is to be gained in that property; the shaft is 1900 ft. deep, and is to be continued to 2300. Without a single exception development has been splendidly promissive this week and showing up good orobodies. The total ore shipments from the Park City mines during June was 5302 tons; the Silver King Coalition and Daly Judge mines being the principal shippers.

Although the Utah Consolidated smelter has been closed for six months, the Company has not entirely escaped attack from farmers residing in the vicinity of the plant. Suits for damages aggregating $39,410 were filed this week. The damage to vegetation alleged is said to have accrued prior to this year. The custom of the mining companies controlled by Jesse Knight and associates in rendering a financial statement at regular monthly intervals is being carried out to the letter. The June reports show: Beck Tunnel, bills payable, $18,006; Black Jack Consolidated, bills payable, $21,125, and an assessment of 3c. per share, Tunnel, bills payable, $18,006; Black Jack Consolidated, cash on hand, $14,348; Colorado Mining Co., bills payable, $51,203; Eureka Consolidated, cash on hand, $1062; Indian Queen Consolidated, cash on hand, $6619; Ibox Gold Mining Co., cash on hand, $32,019; Iron Blossom Consolidated, cash on hand, $39,231; Mountain Lake Mining Co., cash on hand, $25,466; Mineral Flat Mining Co., cash on hand, $1654; Uintah Treasure Hill Coalition, cash on hand, $11,595.

RAWHIDE, NEVADA.
Settling Down to Development Stage.—Account of Leading Properties.

The camp of Rawhide has experienced its boom and has now settled down to the task of developing its mines. The population of the camp has decreased from perhaps 9000, a vast majority of whom were boomers and loafers, to a working body of 2000. It is believed by many that Rawhide will develop a number of low-grade permanent mines.

The Kearns No. 2 M. & L. Co. have a working shaft 350 ft. deep, have cross-cut and proved their ore at the 60-ft. level, also at the 100, 200, and 300-ft. levels. In doing this development work it has taken out and shipped 280 tons which assayed $300.

The Original Rawhide Mining Co., commonly called the Kearns No. 1, has sunk a prospect shaft 125 ft. deep, from the bottom of which ore assaying $40 has been taken. It has now sunk a working shaft 200 ft. deep and is cross-cutting from this level toward the vein.

The Nevada Rawhide Gold Mining Co., known as the Miller lease, has an incline shaft on the vein to the depth of 60 ft. The whole shaft is in ore. Two drifts have been driven from the bottom of the shaft, one 60 ft. to the south and another 45 ft. to the north. A cross-cut from the north drift shows a 6-ft. vein running parallel with the drift, and a cross-cut from the south drift shows a 2½-ft. vein, both of which assay about $50. The company has sunk a working shaft and has driven about 100 ft. of underground workings. The dump contains 450 tons which will probably mill about $50.

The Rawhide Mining & Reduction Co., commonly known as the Murray lease, has a perpendicular shaft 200 ft. in depth. At the 190-ft. level it has cross-cut to the east 80 ft. and to the west 75 ft. At the end of this latter cross-cut there is a vein 12 ft. wide which assays $35 per ton. On July 8 a body of very rich ore was uncovered in the bottom of the shaft, the extent and richness of which have not yet been determined. A shipment of 20 tons has already been made. A 10-stamp mill has been shipped from San Francisco.

The Rawhide Wonder King Combination has opened up a large body of good millling ore, with some shipping ore. The indications are that it will become a large producer. Arrangements are being made to put up a hoist adequate for deep sinking.

The Truxt lease, on Hoogian hill, has one shaft 100 ft. and another 70 ft. deep connected by a drift at the 70-ft. level. It has shipped 40 tons of ore to the Nevada Ore Sampling Co., at Hazen, and is now sending from 9 to 10 tons of ore per day to the Gates-Tyler mill.

The Rawhide Mining & Leasing Co., commonly known as the Big Four, has one shaft 215 ft. and another 50 ft. deep. At the bottom of both shafts are underground workings of a total length of about 350 ft., exposing several veins which assay from $12 to $65.

The Grutt Hill Mint Mining Co. has an incline-shaft 140 ft. deep from the 50-ft. level, of which a 70-ft. drift has exposed a 3½-ft. vein of ore that assays $20. The last 40 ft. of the shaft is in ore that will assay $100. This property has two tons of ore on the dump that will sample $1000 per ton, and numerous other rich specimens have been taken out.
Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Strength of woods increases with the specific gravity—that is, in general, the heaviest wood is the strongest.

To cut a bottle, fill it with oil up to the line at which it is to be cut, heat an iron rod to a white heat and dip it into the oil.

Washing boilers is best done with hot instead of cold water. Many cracks may be traced directly to the sudden cooling of the shell when cold water has been used, and also hot water is more effective and quicker-acting in removing foreign matter from the boiler.

The first practical rock-drill for hard rock, a pneumatic percussive drill, was designed, not for mining, but for tunneling purposes, by Sommeiller for the Mont Cenis tunnel; priority of conception seems to belong to an American, Fowle, who patented such a drill in 1851, and an Englishman, Bartlett, in 1855, but the Sommeiller machine, designed in 1857, was the first to be actually used, in 1861; it seems to have been first applied to mining at Moresnet, in Belgium, in 1863.

The asbestos used in the United States comes almost wholly from Canada, although this country is the largest manufacturer and consumer of asbestos products in the world. The quantity of asbestos mined in the United States is insignificant and plays no appreciable part in the control of the market. The total output for 1907 was only 653 short tons, being the smallest annual production since 1896. The cause of this decline is found in the better quality and the greater abundance of the Canadian asbestos, which completely dominates the asbestos industry of the United States.

The deepest foundations ever put in by the pneumatic process are those of the steel-arch bridge over the Mississippi river, at St. Louis. The caisson of the east abutment was an irregular hexagon in plan, 83 by 70 ft. at the base, and 64 by 48 ft. at the top, and was 14 ft. high. The working chamber was 9 ft. high. The cutting edge finally rested on solid rock 94 ft. below low water. The maximum immersion was 109 ft. 8½ in., requiring an air-pressure of 47.6 lb. per square inch, being a little over three atmospheres and about the greatest pressure under which men can work.

Fire-clay should be tested primarily for fusibility. This may be done with sufficient accuracy for a preliminary examination in an ordinary gas or gasoline-fired assayer’s crucible furnace. The clay should be ground to pass 40-mesh, moistened slightly, and kneaded until just enough plasticity is developed to enable it to be molded. It should be made up into pyramids of the same size as ‘Seger cones,’ which are composed of mixtures of pure alumina with alkanis and metallic oxides so proportioned as to fuse at definite temperatures. These may be ordered from any dealer in assay and chemical supplies. For testing fire-clay use cone No. 22. If the clay under examination passes this test, more elaborate investigation of the chemical and physical properties of the material, requiring the technical knowledge and experience of a specialist, will be necessary.

The base of an oil is said to be either asphalt or paraffin, according as the oil leaves a residue of asphalt or paraffin upon distillation. A paraffin residuum resembles a mixture of lamp-black and wax or tallow, while an asphaltic residuum resembles black pitch. Nearly all asphaltic oils contain paraffin. To test for paraffin, the heavier distillates are cooled in a mixture of ice and salt. If a white solid crystallizes out, it is usually assumed to be paraffin. The crystals may be separated from the cold oil by filtering, with pressure, through a fine wire gauze or cloth. The collected paraffin is washed with a small quantity of gasoline to free it from the heavy oils. Its melting point should be between 40 and 70° Centigrade.

The percentage of sulphur in a burning oil is usually determined by introducing some oil into an Engler lamp, weighing, burning the oil for two or three hours while the products of combustion are drawn through a 5 per cent solution of potassium hypobromite to absorb the gaseous sulphur compounds formed by combustion. The sulphur is found in the solution in the form of potassium sulphate, and may be precipitated as barium sulphate, dried, ignited, and weighed. From the known weight of oil burned, the per cent of sulphur may be calculated. A volumetric method may be used to determine the sulphur, in which case, the gases are absorbed in a measured volume of twentieth normal sodium carbonate solution, and the amount neutralized by the sulphur dioxide found by titrating back with standard acid, using methyl-orange indicator.

Enquiries as to character and attainments of men seeking positions should be answered fully, with conscientious regard both for the rights of the applicant to the benefit of the doubt and to the best word one can truthfully say of him, and for the right of the enquirer to obtain correct information. But as it is seldom possible to know a man’s true character, and as a man may display different characteristics at different times, a statement of this kind becomes in effect no more than an opinion. A reply should accordingly be withheld on the ground of probable liability to the enquirer, unless he should incorporate an absolving clause in his letter, such as the following: ‘‘Any statement on your part as to the responsibility or standing of this party is a matter of opinion and is given as such and solely as a courtesy, from which no responsibility will in any way be attached to you.’’ This leaves open the possibility of liability to the applicant only, from which no trouble can result if adverse judgment be limited to a simple statement of known and demonstrable fact.
Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

Waters, Meteoric and Magmatic.

The Editor:

Sir—Referring to James F. Kemp’s article on ‘Waters, Meteoric and Magmatic’ in your issue of May 23, I wish to say that Mr. Kemp is mistaken in crediting Elie de Beaumont with being the first to ascribe the formation of orebodies to solutions from magmatic sources. The following quotations are from ‘Considerations on Volcanoes,’ by G. Poulett Scrope, published in London in 1825:

"It appears then (see p. 209), that of the solutions of continuity which accompanied the process of elevation, whether in the replicated strata composing the mountain or in their more distant prolongation, the deepest and widest were subject to occasional extravasation of the inferior lava bed; and these remain as dikes or intruded beds, penetrating the strata, often connected with an overlying bed of crystalline rock of a similar nature. Others which were too narrow and intricate to allow of the escape of any intumescent matter in a liquid form, were yet permeable to the vapors and metallic sublimes that rose from this subjacent mass, and were partly filled by these, and partly by rubbish; * * * from their sides and from above, thus giving occasion to mineral veins. The formation of calcareous and other breccias, and veined-marbles, is accounted for by the smallness of the fractures. The still unconsolidated juice of the rock oozing into its cracks and crevices, and filling them with a deposit of finer matter."

Again on page 23: "But of what nature is the aeriform fluid which escapes so rapidly from the exposed surface of the lava; the loss of which causes its sudden consolidation? There need by no doubt, at all events, that it is the same fluid which causes the expansion, intumesceence, and rise of this substance through the volcanic aperture, until in most cases it overflows the lip of this vent, escapes with violent outbursts from its surface, producing jets of liquid lava and red-hot scoriae. The result of all the experiments and observations that have been made during volcanic eruptions, leads to the conclusion that the elastic fluid which plays so important a part in the phenomena of volcanoes is no other than aqueous vapor or steam." * * * (Page 25) "It appears then from what has been stated above, (1) that the intumescence and rise of lava, within the vent of a volcano, is owing to the explosive force of an elastic fluid generated in its interior, (2) that the violent rise and escape of volumes of this fluid through the columns of lava elevated within the vent produces the jets of lava-drops and scoriae which constitute the principal fragmentary ejecta of a volcano, and (3) that the same rapid escape of this same fluid from the lava, when exposed to the air, effects its instant consolidation. From these and other considerations it appears highly probable that it is the intimate combination of this fluid with the solid crystalline particles of the lava, which occasions their mobility, and the consequent liquidity of the mass. There is every reason to believe this fluid to be no other than the vapor of water intimately combined with the mineral constituents of the lava, and volatilized by the intense temperature to which it is exposed, when circumstances occur which permit of its expansion. When, therefore, I speak of the ebullition of lava, I must be understood to mean the vaporization of water, or part of the water, contained in close union with its solid crystalline particles. In the same manner as wet sand, paste, milk, soup, and so forth, may be made to boil, though it is only the water they contain which is really vaporized."

On page 43 he says: "This escape may take place according to circumstances either: (1) by the rise and absolute expulsion from the mouth of the vent of the liquid lava alone—which consists of an assemblage of crystals of one or more minerals, more or less disintegrated and comminuted, merged in a vehicle of steam, proceeding from the volatilization of the water which was intimately united with their texture, or (2) by the partial elevation, and perhaps expulsion of the lava, and the absolute escape by itself of a certain proportion of the elastic vapors contained in it; which traverse the mass of liquid lava and rise from its surface in consequence of their inferior specific gravity." Again on page 172: "The elevation of islands above the surface of the ocean by the expansion of steam in submarine lava is illustrated by the following: (1) An eruption on St. Michael, one of the Azores, in 1638. Other eruptions took place from the same spot in 1691, and in 1720; which produced an island six miles in circumference. (2) That which gave birth to the Isola Nuova, off Santorini, in the Greek Archipelago in 1707. Santorini itself is reported by Pliny to have been produced in the same manner in 236 B. C., as well as two other neighboring islets, Jera and This. These were enlarged by subsequent eruptions. (3) That of Sobrina, near St. Michael, one of the Azores, in 1811. (4) An island thrown up at some distance from the coast of Iceland during the violent eruption from Skaptar Jökul in 1782. (5) A new volcanic island formed in the Aleutian group near Unalaska in the spring of 1814, called Bejuslaw by the Russian hunters."

On page 223 occurs the following: "The waters of the ocean have two sources, namely, (1) that of land springs, many of which are still thermal, others impregnated with silix and carbonate of lime, and so forth, but in the earlier ages of the globe it is highly probable that the water percolating through the heated crystalline rocks, or produced by the condensation of their vapors, both possessed a higher temperature, and was more impregnated with mineral matter. (2) Rain-water. Rain-water has two sources also: (1) evaporation, by which pure water alone is carried up; (2) volcanic vapors, by which mineral substances, as muriate of soda, lime, and magnesia, and sulphate of soda and lime, are carried up in solution and either mingled with
the water of the ocean if the vent be subaqueous, or carried down into it by condensation of the vapors, if they rise from a subterranean source."

Could anything be plainer than Sower's expression of the idea that volcanic or magmatic waters are not of surface or meteoric origin. The other quotations show the relation of magmatic waters to volcanic action and hot springs, and particularly on page 223, where he names the two sources of the waters of the ocean and also the two sources of rain-water. Sower seems to have known more about magmatic waters and its effects than any subsequent writer, and now there appears to be a renaissance of his theories and an acceptance of his point of view near the centenary of the publication of his book. He does not appear to have theorized upon the way in which the magmatic water got into the magma. He accepted its presence as a fact to be reckoned with.

Philadelphia, May 29.

Hiram W. Hixon.

Cornish Pumps.

The Editor:

Sir—Old Timer, in your issue of May 2, discusses E. P. Jones' description of the pumping plant on the Loddon Valley mine, and singularly he suggests the use of an air-receiver on the ordinary beam-engine type of pumping-plant. Undoubtedly an air-receiver on a pump operated by crank-engines is an advantage, and not only increases the efficiency of the engines and the amount of water pumped, but also relieves the pit work from shock and renders break-downs less frequent. However, the air-receiver is a failure when used in connection with a pump operated by a beam-engine. At the Loddon Valley mine, in addition to the double pumps operated by the crank and fly-wheel engine there was a beam-engine of which the following are the details:

Diameter of cylinder..............108 in.
Stroke..........................120 in.
Steam press......................100 lb.
Lift..............................460 ft.
Strokes per minute..............8'/s=500 per hour

This engine was bought second-hand because it was more important to get increased pumping capacity quickly than it was to secure high efficiency, and being available it was bought and erected before the manufacturers would have been able to deliver new machinery of the type required. The pump-column was made of sheet steel, and the valves were of a multiple-valve pattern. The same sort of air-receiver described by Mr. Jones was attached to the pit-work. This plant never operated satisfactorily until the air-receiver was taken off. The column-pipe burst several times, as did the air-receiver on several occasions, so badly that it had to be taken to the surface, and sent to the shop in Melbourne 100 miles distant. In each case, needless to say, the plant was idle until repairs were completed. Before proceeding, it is well to recall the action of the beam-engine pump. The rods and plunger in this case, if my recollection serves me, weighed about 35 tons. The engine simply lifts the rods, and at the end of the stroke their weight actuates the plungers, forcing the water up the column-pipe. As is well known, the inertia of the water has first to be overcome, and the rods start down slowly, gain speed quickly, and at the bottom, when the momentum is greatest and the work to be done least, the stroke ends. The water-hammer is apt to be very loud, and may well cause the cracking of the cast-iron valves. With the Loddon Valley beam-engine plant it was found that the water issued from the column-pipe in a succession of waves. For each stroke there were several waves at irregular intervals, bringing different amounts of water. One day it was determined to put a pressure gauge on the air-receiver, and then a rough indicator-card was taken. The result obtained was horrifying. It showed a pressure over 350 lb. per square inch where the hydrostatic head due to height of discharge accounted for only 195 lb. The card showed that there were several waves corresponding to the waves observed at the top of the column. Here was the trouble; a moving hammering mass of water exerting a pressure nearly double that for which the plant was designed. It will immediately occur to the reader to ask, "this being so with a beam-engine plant, why is it not also true for the crank and fly-wheel engine plant?" It can only be explained in this way; with a beam-engine the operating force is the weight of the rods, and only then because their weight is able to overcome the weight of water to be raised. The action starts with a jerk, compresses the air in the receiver quickly, and the air being elastic kicks back hard enough to momentarily arrest the descending plunger, when, its potential energy having exhausted itself, it again submits to compression and the same action takes place, though on a smaller scale, and at this time the largest part of the water escapes. Even after the stroke is finished the whole body of water in the column is in motion, rising and falling with the compression and expansion of the air in the receiver. As soon as the air-receiver was removed from this beam-engine plant, it worked without a hitch. With the crank-engine, the stroke starts slowly and finishes slowly, and having the momentum of the fly-wheel behind it, the stroke is more positive. The compression of the air cannot stop it, and the water does not surge back and forth as with the beam-engine. Hence there is no shock, but the reverse, and it gives a sweet-running noiseless plant.

Leaving aside the question as to the relative merits of the Cornish pump and the steam and electrical pumps, the experience gained on the 'Deep Leads' of Australia would unquestionably favor the use of the crank and fly-wheel engine, compound or triple expansion, running at, say, 125 revolutions, and transmitting the power through rope drives, thence through toothed gears to the rods. The high-pressure high-speed engine gives a good steam efficiency, and the rope-drive has the effect of taking all the hack-lash off the engine itself. Where the gear-wheel shaft is direct coupled to the engine-shaft, the hacklash inevitable with this class of pumps has a bad effect on the engine itself. The Wahi Gold mine in New Zealand has a large pumping plant.
The engines are of the beam-type, made by Hathorn-Davies, and although they probably give a high steam-efficiency, a mere glance at the two plants will convince an engineer that the type of plant advocated above is preferable. If we were looking at them merely from the standpoint of efficiency, there perhaps would be little choice, but in first cost, cost of foundations, and time required for erection, the advantage is all on the side of the crank and fly-wheel engine. Compared to the electrically operated pump, for moderate depths, there can be absolutely no question that the Cornish pump is the most efficient, other things being equal.

On the Victorian 'Deep Leads' there are two electrically operated pumps, one a Cornish plunger, and the other a three-throw pump underground. Of the two the plunger was more economical than the three-throw, and neither was as cheap as the Loddon Valley steam-driven plant. The electric power used at the Victorian 'Deep Leads' was obtained from a power station four miles away, where there was a first-class plant, operated jointly by three mining companies which shared the expense. The cost of fuel and labor and the general conditions were exactly alike at both properties, yet the advantage lay with the Loddon Valley plant. At some future time I hope to have more to say regarding the relative costs of these plants. The only plant so far erected with rope-drive and with the features suggested above, is that on the Berry United Deep Leads. There are three sets of underground workings at this property driven by the one line of rods, each lifting the water 200 ft., or a total of 600 ft. The plunger is each 26 in. diam. and arranged for a maximum stroke of 10 ft. This, however, is adjustable, and can be set for various lengths from 5 to 10 ft. The height of the working barrel is 17 ft. The suction valve-pot and delivery-valve each weigh 4½ tons, and are 5½ ft. high. The weight of the valve and seat is 15½ cwt. It is more than an average man can do to lift the clack off its seat. With the windbore, stool, and air vessel, the total weight of each set of workings is 35 tons. The clack itself is a departure from the orthodox practice in pumps of this class, in so far as the double clack is concerned. In action the upper clack opens first, then the bottom clack opens, allowing the large volume required to pass freely. As the clanger retards toward the end of the stroke, the bottom clack settles slowly to its seat, the upper clack remaining open until the finish of the stroke. The valves are so designated as to areas and weights, that simultaneous closing at the end of the stroke is impossible, the object being to minimise the shock. This object has been attained, for it is impossible to detect the beat of the valves by holding the hand to the valve-pot while the pumps are in motion. The pump rod carrying the plungers weighs in all 80 tons, and is 600 ft. long. There are enormous strains consequent upon moving and bringing this gear to rest. The pumps, however, run so smoothly that unless in sight of the rod or plunger an observer would not realize that they were in motion. The engine is a cross-compound type, with the power taken off by a multiple rope-drive. A pair of gears, weighing 20 tons, takes the power from the ropes and transmits it to the pump crank. By means of the usual type of bob the horizontal motion is converted into vertical for driving the pump-rod in the shaft. The bob is made of steel and weighs 24 tons. Steam is provided by a pair of Babcock and Wilcox boilers, with superheaters, having a working pressure of 125 lb. The engines are arranged for condensing, the condenser being of the Admiralty type, and the air-pump and circulating-pump being independently driven. The speed of the engine is controlled by governors instead of by throttling, as is the usual style of pumping-engines. A series of pulleys are provided so that the number of strokes can be maintained at from five to ten per minute, as desired. The speed being controlled automatically by the governor, this gives almost as good a steam economy for the low as for the high speed.

London, June 5.

**Flotation Processes at Broken Hill.**

The Editor:

Sir—In your issue of April 11 is an article on 'Flotation Processes at Broken Hill,' from an 'occasional contributor,' which says that the Potter process is now consolidated with the Delprat interests, and that the Delprat process has now become a thing of the past; that the Broken Hill Proprietary is using the Potter process only, and, further, that there is a persistent rumor at Broken Hill that the Proprietary is using two tons of oil per day in this process. Knowing how anxious you are to give correct information in your valuable paper, you will allow me to point out that your correspondent has been misinformed. The Delprat process has put through up to now about 800,000 tons of material, and continues to treat about 1200 to 1500 tons per day, producing about 1 ton of 42% concentrate to every 4 tons of feed. Further, no oil is used at all, and the only pans employed are those patented by myself, and to which the Potter company lays no claim. The process is not "quit dead," but will be dead as soon as we can find one giving more paying results.

E. D. DELPRAT.

Broken Hill, New South Wales, June 2.

**The Mond Nickel Co., operating in northern England.**

has made remarkable progress recently and further evidence of its prosperity is given by the dividend declared last month. The distribution on the ordinary shares, which a year ago was 12½%, is increased this time to 15%, while the deferred shareholders will receive 48, as against 33%. At the same time £25,000 is placed to reserve, as compared with £80,000, and the balance carried forward is £11,600 larger than last year amounting to £29,900. Considering that the first dividend on the ordinary shares was declared only three years ago, and that two years before then the preference interest was not fully earned, the progress made since the initial difficulties were overcome has been astonishingly rapid.
MINING THE TREADWELL LODE.

Written for the Mining and Scientific Press by T. A. Beckard.

The ore deposits of Douglas Island, in southeastern Alaska, which have been made famous by the production of the Alaska Treadwell Gold Mining Co., are interesting to the miner as an example of the exploitation of immense masses of low-grade gold ore. This ore occurs in the form of irregularly lenticular bodies, encased in schist, the quartz itself being a replacement in diorite. But I shall not try to describe the geological features; the purpose of the present article is to give an account of the methods adopted in the mining of wide orebodies without the aid of timbers. Fundamentally, the method of mining used in the Treadwell mines is the application of the overhead system of stoping to an unusually large low-grade deposit of gold ore. The ore is staked to a maximum width of 250 ft., and it has been removed for a width of as much as 160 ft. for a length of 300 ft. Owing to the diffuse impregnation of the diorite the shape of the cavernous openings made in the course of mining is determined more by the assay of the rock than by any definite boundaries or structural lines. If the quartzified diorite carries $2 in gold, it is ore; if it carries 50 cents, it is waste rock; between these limits there is a line of demarcation made by the fact that the total working-cost is $1.35 per ton.

Fortunately, the gold-bearing rock constituting ore will stand without the support of timbers, because it is not only hard but also comparatively free from cross-fractures; and although lime-feldspar exists with the quartz there is not enough of it to cause rapid weathering. To the miner it is "good ground." If the lode had a thickness not exceeding the usual staking width of 4 ft., no precautions whatever would be necessary, but owing to the immense size of the openings made underground in the course of staking, and the consequent overhang of the rock on the upper side of the lode, there is bound to be heavy pressure and eventual caving, unless pillars are left. The ore has a dip of 50 to 65° northeast, and conforms to the general strike of the country-rock. On the hanging-wall side there is greenstone or gabbro, harder than the schist and limiting the impregnation of gold-bearing quartz southward. On the foot-wall the schist is fissile and soft, the limit of ore is ill-defined, and the ground is heavy. If a small thickness of quartz is left on the "foot," the ground stands well, and as the ore is very low-grade it pays to run no risk by stoping too far in that direction.

The stopes are advanced upward in the shape of large rooms separated by pillars. These pillars are from 18 to 25 ft. thick, at right angles to the longer axis of the orebody, and flaring at both walls, as shown in plan in Fig. 1. The idea is to place them in alignment, that is, vertically continuous from level to level. But before describing the stoping, it is necessary to state how the shaft is sunk and stations cut. This is an important matter. The shaft is vertical and in the foot-wall country. When the shaft (10 by 24 ft.) is to be deepened, the first thing is to construct an A-shaped bulkhead of heavy timbers 14 by 20 in. (Oregon fir) across the shaft, covering all of it except a sinking-compartment, which is 4 by 6 ft. inside of timbers. In Fig. 2 the compartment is not shown, as the section is taken across the length of the shaft. The bulkhead is loaded with loose rock to the apex, and as much as 10 ft. over it. Next, the sinking-compartment is put down about 40 ft., and a pillar 20 to 30 ft. high is left for the full width of the shaft and the full length, less the sinking-compartment. This is called the penitice. A recess is cut in the top of this penitice and a tank built with 3 in. plank, tongued and grooved and braced by rods. No cement is used. This tank serves to catch the water dripping down the shaft. On the tank a pump is erected.

The top of the penitice is 60 ft. below the floor of the skip-chute station of the last level, the penitice is 30 ft., and the distance from the bottom of the penitice to the floor of the shaft-station is 65 ft. From the shaft-station to the floor of the next skip-chute station is 45 ft., making 200 ft. in all.
The shaft having been sunk 65 ft. below the pen-
tice, two rounds of holes are driven, making a
space (A B G H) the size of a drift (7 by 10 ft.) and
usually 7 ft. long. This is done on both sides of the
shaft. Next, the shaft is sunk 45 ft. and a station
(C K D L) cut, 10 ft. deep, and the width equal to
the biggest dimension of the shaft. This will be the
station for the chute that will load the skips. Now,
a raise is put up to connect with the upper opening
(A B G H). This establishes ventilation. From the
raise the ground is stoped in the form indicated so
as to make a big pocket (C E B) with a flat arch,
which ultimately forms the roof of the station. The
distance from B to E is 30 ft. Timbers are placed
in position and car-tracks are laid across them. The
height of the arch at F is 20 to 25 ft. above the track.
The length of the opening in a direction at right
angles to E B is 60 to 80 ft. As soon as the raise
has progressed the height of two rounds of blasting,
the chute to deliver the ore into the skips is built.
A similar pocket for waste is cut on the opposite
side of the shaft.

The shaft-stations being completed, a cross-cut (7
by 10 ft.) is started and run through the orebody
to the hanging wall, as from A to C in Fig. 3. Where
the cross-cut passes through the foot-wall, a drift
(7 by 10 ft.) is extended eastward along the foot-
wall and partly in it. The position of a pillar hav-
ing been determined relative to an existing pillar
vertically overhead (on a level above), a raise (6 by
7 ft.) is started in this future pillar (at D) and con-
nection is completed with the level overhead, so as
to establish ventilation. The levels are 200 ft. apart.
Originally they were only 110 ft. apart, but, on ac-
count of the cost of opening up successive levels, it

---

Cutting out Stope, with Opening Around Chute-Raise in Foreground.

Flashlight Photograph in Alaska Treadwell Mine.

was found economical to increase the interval.

The making of this first raise must be described in detail: The raise is always placed in the pillar nearest the first cross-cut, so as to stimulate ventilation. The main raise is put up 18 to 20 ft.; then on the side farthest from the cross-cut at a distance of 25 ft. from the raise, another raise (K) is made to a height of 18 ft. and an intermediate drift run so as to connect the two raises. See Fig. 4. A chute is then built at the bottom of the first raise (D) and a substantial ladder-way placed in position in the second raise (K) to serve as a man-way for the miners at work in the main raise (D), which is then extended upward. The first section, or bottom 20 ft., of the main raise serves as a pocket for the ore broken in the raise as it is extended upward. As the raise goes up, blind drifts (made by two rounds of holes) are driven on either side at intervals of 30 ft. These serve as stubs for future intermediate levels, and obviate injury to the raise itself from blasting on the stope side, when connection is made with the intermediates.

The foot-wall drift has been extended to the first pillar, that is, from B to D. The drift is now continued along the foot-wall to the boundary; main raises are made at intervals of 200 ft. and at the boundary (E). All the raises are in ground intended to serve as pillars. At some convenient point, not in a pillar, and usually midway between two pillars, a cross-cut (F G) is driven from the foot to the hanging wall. Next, at intervals of 60 ft., drifts are run in both directions, parallel to each other and to the longer axis of the orebody, as far as the limits of pay-ore, as determined by sampling and assaying. These median drifts connect westward with the first cross-cut from the shaft. From that cross-cut similar drifts are extended to the western limit of the ore. At a point conveniently near the hanging wall, and at about the centre of the orebody, a main raise (H) is made from a drift, in a pillar, to the level overhead, so as to ventilate this part of the mine. From the drifts and cross-cuts, at 25-ft. intervals, blind raises are put up 18 ft. (three rounds of holes); these will serve as chutes, and are termed 'chute raises.'
This finishes the work on the level. All the work is done on contract at an average price of from $8 to $8.50 per foot of drift, cross-cut, and raise. The man-way raise costs $10 for the first 100 ft., and $11 for the remainder.

The lowest portion of the main raise (D) is now emptied, (Fig. 4), so that the ladder-way can be carried down to the level itself, instead of to the intermediate drift, as heretofore. A machine (M) is now put to work on the intermediate at the top of the chute-raise and also (N) at the breast of the stub drift on the other side of the pillar. As space is cleared other machines are brought into service. Thus a cutting-out stope is carried forward with a height of 8 ft.; it breaks successively into the tops of the various chute-raises and is extended as a floor until it reaches the next pillar and then northward to the limit of the ore. The ore broken in this cutting-out stope has to be shovelled into the chute-raises, from which the ore is drawn into ears and taken to the surface. The chute-raises are kept full, to protect them.

Before stoping the ‘back’ over the cutting-out floor, it is the custom to enlarge the tops of the chute-raises so as to make a funnel-shaped opening. This is done with machines on a tripod. This first stope is now ready for back-stoping. In enlarging the stope upward, connection is made with the stub drifts driven from the main raise, as previously described.

In beginning to back-stope, the machines are set up in the centre and a cut is taken for the full length of the stope, so as to begin to shape the roof in the form of a flat arch. Then the ground is broken both ways toward the pillars, each successive cut tending to maintain the arch with which the stope was started. As the ore is broken down and the larger fragments reduced by sledge-hammers and ‘bulldozing,’ it accumulates. One third of the broken ore can be removed and yet leave sufficient in the stope to fill all the cavity, save that needed for working. When in place 12½ cu. ft. of ore will weigh one ton; when broken, this ton of ore will uncooty 16 to 18 cu. ft.; thus, the broken ore requires one third more space than the unbroken. This ratio is maintained throughout the mine.

The stope is gradually extended until it breaks into the level overhead, but the opening is restricted so as to flare the top of the pillar and leave a shelf projecting around the stope. The top surface of this shelf is the cutting-out floor of the stope as started at the upper level. See Fig. 5. These shelves are called ‘sheet-pillars,’ but they are truly pentice, for they are intended to protect the men occasionally at work in the stope underneath during the process of drawing the broken ore.

The pillars are 100 ft. apart, centre to centre. A main raise, with man-way, is made in alternate pillars. While the chute-raises are intended to be 25 ft. apart, they are placed so as to be of maximum service in working any given block of ground and they are pointed at different angles, to accomplish their purpose. It will be understood that the system is modified according to varying conditions, for instance, if a horse or wedge of barren rock divides an orebody, the drifts are driven at wider intervals, and the spacing, height, and angle of the chute-raises is so adjusted as to obviate excessive shoveling of ore in the stopes. As far as possible, all drifts are driven in ore, so that unproductive development work is reduced to a minimum. Of course, only an experienced mine manager knows how to modify such a system to local necessities; without proper knowledge any system is certain to be a snare and delusion.

The practical application of this system of mining is shown by the plans of the 900 and 1050-ft. levels of the Alaska-Treadwell mine. On the 900-ft. level, the ore-mass is as much as 250 ft. wide on the south orebody; there are four parallel drifts, one main cross-cut, and another cross-cut on the edge of the orebody in front of the shaft, which happens to be in ore. Four rooms have been excavated, these are known as No. 1, No. 2, No. 3, and No. 4; they are 120, 130, 100, and 60 ft. lengthwise, and 150, 170, 180, and 200 ft. across, respectively. The pillars are approximately 18 ft. thick, flaring notably in their approach to the sides of the stopes.

For the details of this description I am indebted to the courtesy of Robert A. Kinzie, general superintendent of the Alaska Treadwell Gold Mining Company.

STEAM-PIPE COVERING IN A WET SHAFT.

Written for the Mining and Scientific Press
by E. P. Kennedy.

In order to obtain a covering more substantial and effective than the magnesia covering commonly used, I recently adopted wood-stave pipe, the internal diameter of which was somewhat larger than the external diameter of the steam line. The individual staves were thoroughly painted before using. The steam-line was wrapped with asbestos paper, held in place with string, and then the wood staves were placed around the pipe and drawn to place by a clamp at each end. Galvanized iron wire was then wrapped spirally around the staves, and made fast by staples, driven into the wood. The clamps were then removed to proceed with the next section. The labor in putting the staves on is probably a little more than that required for adjusting regular pipe-covering, but, by having the clamps which pull the staves into position hinged on one side, and provided on the other with a swing-bolt, the staves can be put on quite rapidly. The cost of material is less than one-fourth as great as magnesia pipe-covering.

No attempt was made to compare efficiencies. However, by using wood-staves of a diameter larger than the iron pipe, and by using asbestos rings or gaskets between the iron and the wood-pipe a dead-air space is obtained, which is the effect aimed at in all of the pipe-coverings on the market. Magnesia pipe-covering can be protected more or less effectually by a housing of tin or galvanized iron. This is done at considerable extra expense and with not always satisfactory results. The wood-stave covering, on the other hand, will withstand a great deal of rough usage, and is exceedingly durable.
EXPERIMENTAL MILL OF THE NEVADA CONSOLIDATED COPPER COMPANY.

Written for the Mining and Scientific Press
By M. L. Kesqua.

The two problems that were necessary of solution before the future of the Ely district could be assured were, first, tonnage, and secondly, the concentrating value of the ore. The district was remote from railroad transportation. Eureka, then the nearest railway station, is 85 miles to the west, but railway construction from that point was never seriously considered, because of the much more favorable though longer route from Cobbe, on the Southern Pacific, 140 miles north of Ely. This road follows the Steptoe valley, has a maximum grade of 0.7%,

experimental curves of 6°, and practically neither cuts nor fills. Against this the Eureka route would have had four summits to cross, with a maximum grade of 4%. The investment was of necessity large, in order to put the property on a producing basis, and it was not conservatism to leave anything to chance. It meant at least $2,000,000 in the railway, $2,500,000 in plant, and $500,000 for mine equipment, or a total of $5,000,000.

To justify this investment for a deposit of low copper content, demanded millions of tons of developed ore, and absolute knowledge as to its concentrating value. The question of smelting was not one that needed actual demonstration, as it was well known what could be done with such concentrate, but while similar ore was being concentrated in other places and the results known, it was deemed necessary, in order to make possible the financing, that a small experimental concentrating mill be erected and actual tests made. The ores of the Ely district, as is now well known, are almost entirely concentrating. The amount of direct-smelting ore developed is comparatively small and insignificant. The future of the camp is dependent entirely upon success in concentrating its ores to a satisfactory saving. A small experimental mill was erected at the collar of the Ruth shaft. This mill consisted of a grizzly, on which the mine-car was dumped and the larger lumps of ore broken by hand. From the ore-bin the ore was fed by a plunger feeder into a trommel. For the purpose of experimenting, screens of various sizes were used, and it is probable that some of these experiments were not wisely made, and this is one of the reasons for believing that in a large mill, prop-

expectation that a profit would result commercially, the mill undoubtedly gave a very fair test as to what could be expected from the ores when treated on a large scale in a mill fully equipped for handling the ore in the most economical manner. The test also resulted in a complete re-sampling of the mine in sections of practically 30 or 40 ft. Each level was taken by itself, and the test made consisted of ore taken along a drift or cross-cut as nearly equal as possible over a length of 30 or 40 ft. Every eighth shovelful of this ore was thrown upon a sample-sheet at the head of the mill, and at night before the mill was finally closed, this sample was coned and quartered in the usual way, and the remaining portions of the sample put through the plant. The mill was sampled every half-hour, and thoroughly cleaned up every night; that is, samples were taken of the feed into the first compartment of the classifier, of each machine-heads and tails, of the round-tank slime, and of the tailing down the canyon. These samples were carefully decanted, dried over night, and assayed the following day. The mill was operated for two or three days before being put in regular commission on September 11, 1904, and was operated daily thereafter until December 1, during which time 48 separate recovery-trials were made. The re-

results on all of these tests are set forth in the table herewith. The percentage of copper in the shovel-sample refers to the percentage in the shovel-sample, being every eighth shovelful of ore that was shoveled onto the grizzly. The map-average refers to the samples that were taken from day to day as the mine was developed, over every five-foot section. It will be noted that the map-average is somewhat higher than the shovel-sample, and considerably higher than the average of the percentage of copper in the crude ore, which was the sample taken every half-hour from the spout of the Huntington as it discharged into the first compartment of the classifier. A daily detail-sheet was compiled showing the work of each machine, a copy of one of which is presented hereto. Unfortunately, this is the only detail-sheet in existence, the originals all having been destroyed in the San Francisco fire.

It is an interesting fact that the result of some 150 assays made by the cyanide method, and compared with the same number from the same pulp made by the iodide method, showed a variation of 0.12%, the iodide being the greater. Cyanide was found to be entirely satisfactory on low-grade mate-
rrial, but upon the concentrate it was found that the
results were erratic and always low, although in
some cases the variation was very slight. Sixteen of
the lots-samples were sent to the Tennessee Copper
Co. to be assayed by the electrolytic method. By
this method lots No. 2 and 3 were found to contain
1.65% and 1.92%, respectively, more copper than
our assays showed. Of the 16 samples sent to the
Tennessee Copper Co., 15 ranged from 0.61 to 2%
higher in copper than we had been able to get by
the cyanide assay on the ground in Nevada. It is
possible that some of the variation between the map-
average and the mill-head may have been due to the
fact that there was a certain amount of soluble cop-
per in the water, which was precipitated upon the
iron through the mill, or went down the canyon with
the tailing.

I believe unquestionably that in the large mill now
being built these results will be materially bettered,
as it was not possible to treat the products of various
sizes from our classifiers as we would like to have
done, nor was it practicable to put in re-grinding
machines for re-grinding the coarser products, owing
to the fact that the fall between the top of the mill
and the bottom of the canyon was limited, and that
it was not practicable for these preliminary experi-
ments, to put the mill elsewhere. We found it
impossible to install intervening V tanks, settling
boxes, classifiers, etc., as would certainly be neces-
sary to secure the best results. It seems fairly evi-
dent from the results of these experiments that a
large mill should yield above 75% extraction. This
being the case the cost to the Nevada Consolidated
Copper Co. of its copper, taking into consideration
the steam-shovel work at Copper Flat, and the
caving at Ruth, should not exceed 7½ or 8e. per
pound sold in New York. Assuming a recovery of
30 lb. per ton, we would have on a 15e. copper mar-
et, 7½ per pound profit, or ½2.10 per ton of ore.
Assuming 15,000,000 tons of actual ore blocked out
in the property, this would give a net earning ca-
cacity of something over $30,000,000, or figured
upon the present outstanding stock, plus the 200,000
shares reserved for conversion of railway bonds,
and 300,000 reserved for conversion of mining
bonds, or a total of 1,600,000 shares, a net dividend
of approximately $20 per share from ore now de-
veloped. In addition to ore now developed, or
actually blocked out by drifts, cross-cuts, and raises,
bore-holes have demonstrated the existence of a
probable tonnage which, when blocked out, promises
to greatly exceed the tonnage already developed.

In addition to this the Company has an acreage
unprospected far in excess of the area known to con-
tain ore, all within the porphyry area, and all possi-
ibly ore-bearing. The developed ore lies entirely in
the Ruth, Fraction Tunnel Site, Blair, Eureka, Star
of the West, and Star claims. The total holdings of
the Company comprise 63 claims, giving it the heart
of the district and an ore-bearing area in excess of
the combined area of all the other companies operat-
ing on the mineralized belt. It would be foolish
to attempt to forecast the ultimate tonnage that
may be developed.

While this article has been in preparation, the
concentrating and smelting plant has gone into com-
mision, and preliminary results seem to confirm
the work of the experimental mill in every respect.
The roasters are doing more than expected of them,
and the reverberatory furnace is approximating the
best Anaconda practice.

**CONCRETE BOATS AND BARGES.**

*An interesting little item has appeared in the
newspapers and technical journals from time to
time concerning a concrete boat made in France
some years ago. Barges and pontoons of cement
were also constructed on the Tiber by Messrs. Ga-
bellini, of Rome. It is stated that concrete in this
application as in building construction, has many
advantages. The method of construction is simple
and the boats are quickly made, at less cost than
those of wood or steel. They will stand very rough
usage, are practically indestructible, and, of course,
are fireproof. It is also said that the smooth surface
of the cement-finish offers less resistance than wood,
and that the bottoms do not foul easily or collect
seaweed. Consequently they are easy to clean. In
case of damage to any portion of the boat repairs
are quickly and cheaply made with cement or con-
crete. A comparison of cost with steel barges has
shown that the concrete boat can be constructed at
half the cost and that in the matter of maintenance
the cost is about a fourth or a third less.

As examples of the boats constructed the ‘floating
chalet’ for the Rome Rowing Club was built in
1897 on pontoons, and has a length of 67 ft. with
a beam of 21 ft. The posts and roof are of concrete,
re-inforced with expanded metal. The Lignura is
a barge of 150 tons, and was constructed by Messrs.
Gabellini in 1905. Since January, 1906, she has been
working in the harbor of Civita Vecchh, near Rome.
In October, 1905, she was towed from Rome down
the Tiber to the sea. She was also towed to Genoa
and Savona, after which she was towed back again
to Genoa and Civita Vecchh. A 100-ton barge was
constructed on order of the Italian Government in
1906. She was tested in the military harbor of
Spezia, and was so successful that a contract was
placed for four more on the same lines. These par-
cular barges have a double sheet, forming water-
tight compartments, and are practically unsinkable.
Their dimensions are 51 ft. long by 16 ft. beam.
Smaller pontoons have been built in large numbers.
In America conrete boat-building is an entirely un-
developed enterprise, but that it offers great possi-
bilities would seem to be indicated by the success
attained in Italy.

Metallic vapors begin to condense at temperatures
depending upon the vapor-tension curve of the
metal and the amount of other noncondensable gas
with which it is mixed. These intermixed gases re-
duce the pressure upon the metallic vapor, and
lower the temperature at which the vapor becomes
saturated. The phenomenon is exactly analogous to
the ‘dew point’ of air and the precipitation of rain.

*Abstracted from *Cement Age*, June, 1908.
GOLD MINING IN PORTO RICO.

Written for the Mining and Scientific Press
By William B. McKinlay.

The search for gold has, for centuries, been one of the keenest quests of mankind. The pages of history are indelibly marked with witness to this truth; moreover, they are marked in letters of scarlet, for the gaining of the yellow metal has almost everywhere been accompanied by the shedding of human blood. The most striking period in history, as regards the search for gold, may well be stated to have been the time of the discovery and conquest of America. Volumes have been written on this subject, many of which have been quite as interesting to the casual reader as to the student and scientists who have scanned the pages in the hope of seeing old facts brought forth in a new light. How many have thus been spurred on to join the Argonauts in the never-ending search for the Golden Fleece? And yet again, how many lambs have been snared of their own precious fleece by perusing the fascinating literature of some of our modern promoters, in which a few facts are so skillfully built up that the whole structure has the semblance of truth?

A noteworthy example of a fallacy constructed on some substantial facts, although in this instance without evil intent, is the oft-repeated story that gold was first discovered in California in 1848 by a workman digging in a mill-race in the Sacramento valley. This has been so thoroughly drummed into the minds of the school-children of the United States that it would seem almost sacrilege to dispel the illusion. Yet it is an indisputable fact, vouched for by the records of the San Fernando Mission, that gold was discovered and mined in what is now California as early as 1842, and probably fifteen years earlier. A book entitled 'Life in California,' published in 1846 by Wiley & Putnam, of New York, gives a very clear account, on page 190, of placer mining near the San Fernando Mission, and of what was at that time considered to be the first mine which was discovered in California. If such a misconception of comparatively recent events can be so generally entertained, is it surprising that many salient facts concerning the history of the first discovery and mining of gold by Columbus and his followers should remain comparatively obscure and almost entirely overshadowed by later events!

The first gold seen in America by the conquerors was worn by the natives of Watling's island, or Guanahani, where Columbus first landed, on Friday, October 12, 1492. Here, and in the neighboring islets, were seen gold ornaments which several of the inhabitants wore suspended from the nostrils. In at least one instance the nose ornaments bore certain marks resembling letters, which led Columbus to believe that it was used as money; but subsequent investigations convinced the Spaniards that money, in the European conception, did not exist among these aborigines. Such conversation as could be carried on by means of signs led the discoverers to understand that to the south lived a great king, in whose dominion existed an abundance of the metal which excited the curiosity of the newcomers. So, as hounds follow the scent, they turned their vessels toward what they believed to be Cipango (Japan) and discovered the island known to the natives as Cuba. They were well received here, and sent a small company into the interior, to the residence of a chief or Cacique, where they saw many gold ornaments of various kinds. The chase was not at an end, however, for the Cubans of that age pointed to the east and said bohó when asked about the gold. They meant the island which was known to them as Aytí, where there were many houses; the word bohó, in their language, signifying a house. The Spaniards also understood the natives to say Cubanacán, and for a time they thought it referred to Kublai Khan, the ruler of the Mongolian races in Asia; but it was finally interpreted to mean the interior of Cuba. Consequently they spent some time in Cuba, landing at different points, but eventually continued eastward.

Martin Alonso Pinçon, commanding the Pinta, became impatient and left the others on November 21, but was afterward overtaken. At one port where a stop was made Columbus saw some stones which apparently contained a little gold, but it seems that he did not consider them as important as gold accompanied by rock. He called the bay Santa Catalina, and the locality is in what is known today as the Province of Holguin, north of Santiago de Cuba.

The Santa Maria and the Niña proceeded eastward, hoping to rejoin the Pinta. On December 6 they made a brief stop at the northwestern extremity of Aytí, which island they named Española. They skirted around the north coast and entered a bay opposite a small island, which they called Tortugas on account of the tortoises seen in that vicinity. The natives fled, but the Spaniards managed to capture a woman who wore the now familiar golden nose-ornament. As the Spaniards treated her kindly, she spoke highly of them to her people, who then gave the newcomers a hearty welcome. Here again the natives pointed to the east when asked where gold was obtained. About two weeks were spent at this place, cultivating the natives in a social way, bartering trinkets for gold, and refitting the vessels for a continuance of the voyage. Another stop was made a few leagues away, where a native king, Guanacanagari, entertained them royally. One calm night, while even the helmsman slept, the Santa María drifted ashore and was wrecked. Guanacanagari rendered every aid possible, and saved practically everything of value. As the Niña could not conveniently accommodate the crews of both vessels, it was decided to establish a colony among the natives. The timbers of the ill-fated Santa María were used to build a fortress, and 39 men volunteered to remain, under the leadership of Diego de Arana. This first colony known to have been established by Europeans in America was left to shift for itself on January 4, 1493, on the north coast of what is now the republic of Hayti. It was called La Navidad, as the Spaniards arrived there on Christmas day.

Sailing toward the east, the Niña fell in with the Pinta on second day. Pinçon gave an account of his
adventures and of the gold he had obtained by bartering with the natives; and although Columbus always maintained a bitter resentment, Pinçon was nominally forgiven for his desertion. The two vessels touched the coast at different points, and at the last port the first bloody conflict took place, several natives being killed before the rest were 'pacified.' After securing more gold by barter, and such provisions as could be obtained, the Niña and the Pinata set sail for home, carrying Indians from different islands they had visited. When they had sailed about sixteen leagues from España, the Indians pointed out the island of Boriquen, which some of them called Carib, and told of the gold which might be found there, but Columbus respected the wishes of the majority and continued on toward Spain.

On his second voyage Columbus landed on the island of Boriquen and gave it the name of San Juan Bautista, or, as we would say in English, St. John the Baptist. This name became shortened later to San Juan; and still later the island and its capital city, Puerto Rico, gradually changed names with each other. Although Columbus knew, from the accounts of the Indians, that the island must be rich in gold, he hurried on to España, to render assistance to Diego de Arana and his little band of colonists.

The early history of Boriquen is to a great extent intermingled with that of España. The island of Boriquen was somewhat neglected for several years, although not entirely so. Many of the vessels which passed between España and Spain stopped for water at or near the port which in later years became known as Aguadilla, that is, the little watering-place. While on a voyage of exploration, in September, 1493, Columbus landed on Mona island, which has come to be considered as a part of Porto Rico. The voyagers found on the island some very fine large melons; and this was by no means the last instance in which the directors of an American mining enterprise cut a few melons before actual mining work began.

In 1499 Alonso de Ojeda started from Seville on a voyage of discovery, among his party being Amerigo Vespucci. According to Herrera's 'Historia de las Indias Occidentales,' they stopped at the island of San Juan on the way home and carried 222 of the inhabitants to Seville, but it does not appear that Ojeda tried his luck at mining on the island. During the years immediately following the early settlement of España, it is probable that many individuals desired to settle on the adjacent island of San Juan, with the hope of enriching themselves by working the gold placers talked of by the Indians. On April 24, 1505, a contract was made with Vicente Yañez Pinçon, in consideration of the services he had rendered in the conquest of España and in explorations and discoveries, giving him the right to colonize the island of San Juan, under certain conditions, and appointing him captain and chief magistrate of the island. Pinçon took Martín García de Salazar into partnership with him, and they started a cattle ranch, and made a half-hearted attempt at developing the island, but do not seem to have done any active mining. Pinçon evidently preferred the exploring business, for he continued at sea, and in 1507 was appointed a 'royal pilot.' As it was but a short distance from the east coast of España to the island of Boriquen, the natives passed from one to the other in canoes at frequent intervals. In 1508, Captain Juan Ponce de León, residing in Higuer, the most easterly province of España, heard from some of his Indian servants that there was much gold on the island Boriquen. Ponce de León had come from Spain with Columbus on his second voyage, and had acquired no little wealth and influence in España, particularly on account of his military service, having been appointed lieutenant-governor. When Ponce heard of the abundance of gold in the neighboring island, he quietly obtained permission from the governor, Nicolás de Ovando, to investigate, and to see what the possibilities were for colonizing the island. Ponce was a very diplomatic financier, and gave the natives what might, in modern slang, be called 'the glad hand,' and it is reasonable to suppose that he opened wine. At any rate, Guaybana, the cacique, showed him some of the gold mines of the island. It was not a prospecting trip, in the modern sense. Guaybana had a controlling interest in several excellent placer-propositions, and expected to sell his rights for the good will of the Spaniards, evidently supposing that the good will would be perpetual, and that he was doing a service to his country in making such a bargain; but the Spaniards failed to fulfill their part of the implied contract. Guaybana showed Ponce several rivers where gold was found, and especially two that were very rich. Ponce took samples to show to Ovando. Several Spaniards were left on the island, to keep Guaybana and his people in good humor, and perhaps to prevent other parties of Spanish explorers from trying to drive a bargain with the natives. Of the rivers, only the Cebuco seems to be positively identified. It is on the north coast of the island, and gold placers have been worked there in recent years, near the town of Corozal. As to the other, called the Manatubó, some writers have insisted that it was also on the north coast, but the majority have described it as being on the south side of the island, and as flowing into the sea near Cape Mala Pascua. The Maunabo river fits this description, and the names are similar. Fray Íñigo Abbad, who wrote in the eighteenth century, says that Agusyabana showed Ponce the rivers from which they obtained gold, especially the Manabón, which debouches on the south coast, adjacent to the cape of Mala Pascua; and the Sibuco, which empties on the north, to the west of the capital city.

Ponce de León arrived in España with his samples of gold, which, after melting, showed a value of less than 450 maravedís to the peso. While not quite as pure as that which had been found in España, it was considered very good; especially as there appeared to be a great quantity available in the island of San Juan. The maravedís is difficult to define. There have been maravedís of gold, of silver, and of copper; and the value of the silver and copper maravedís fluctuated between wide limits.
However, about the time of Ferdinand and Isabella, 490 maravedis was the value of a gold peso or castellano, presumably 900 fine.

The peso or castellano was a unit of weight and was equivalent to 4.6 grams; so that, in terms of our money, a peso of pure gold was worth $3.94. The gold shipped from America to Spain was never pure, and the fineness probably varied between 700 and 900, and in estimating the modern value of the pesos of gold that were shipped, limiting values of $2.13 and $2.74 should be taken. Assuming the fineness of the gold to have averaged about 855, $2.60 may be assumed as the average value per peso of the gold shipped from the West Indies.

Although conditions on the island of San Juan appeared favorable to Ponce de León, he was destined to have his troubles. Diego Colón, the son of the discoverer, and chief admiral, was hostile to Ponce and to Nicolás de Ovando, and deposed the latter from the governorship of Española. Ponce returned to his new island, taking his wife and daughters with him, and proceeded to govern the island by right of occupation. The news of Ponce's exploration having reached Spain, permission was given to Don Cristóbal de Sotomayor to go to the island of San Juan and to take as many settlers as he pleased. At the same time Lope de Conchillos was appointed melter and marker of gold for the island. Diego Colón refused to recognize the credentials of Sotomayor, who arrived from Spain with an appointment from the King as governor of San Juan. Diego appointed Juan Ceron and Miguel Diaz as his representatives to govern the island, where many colonists had now settled. Ceron and Diaz managed to hold their respective offices of judge and sheriff for nearly a year. Meanwhile Nicolás de Ovando had appealed to the King in behalf of Ponce. The King had written to Ovando on May 3, 1509, urging that Ponce keep up his good work in developing the island. On August 14, 1509, the King sent him an official appointment as provisional governor, with the assurance that the Admiral would not have the power of removal. Notwithstanding the political wrangling, the new settlers commenced mining in earnest, and the natives were pressed into service.

The Spaniards devised no mechanical contrivances to extract the gold, but organized the work in such a way as to get a large yield by the methods already in use. Each Spanish miner acted as a foreman and divided his native force into three gangs. One gang loosened and excavated the gravel, and another gang carried it to the third, known as the washers.

The instrument used was the batea or gabata, a bowl hollowed out from a single block of wood, in shape similar to a common bread bowl, but more elliptical, and with projections at the ends by which to grasp it.

For several years the Spaniards contented themselves with working the deposits in the beds of the rivers, which they diverted temporarily from the usual courses. They also worked the gravel deposits near the rivers. They would stake out claims in squares or rectangles, excavating the ground in successive layers, testing each layer of 6 in., and discarding or washing the entire layer according to the results of the tests. Excavation continued to bedrock, or until it became necessary to abandon it because of the caving of the ground or the excessive quantity of water encountered. They never thoroughly exhausted the ground, and it may be said that the island is as virgin today as it was before the arrival of the Spaniards.

(To be continued.)

RARE-EARTH MINERALS IN TEXAS.

In the middle of the Llano region, which is an 'island' of pre-Cambrian rocks in almost the geographical centre of Texas, stands one of the most remarkable natural mounds in the United States. This mound is known as Barringer hill, and is celebrated for its content of what geologists term 'rare-earth metal minerals.' In a short description of this hill, which is formed by a dike and is only about 40 ft. high and 100 by about 200 ft. in lateral extent, F. L. Hess, of the U. S. Geological Survey, in Bulletin 340, just published, gives a list of about two dozen minerals found in this small area, among them a number of radio-active minerals. Among the rare-earth minerals found at Barringer hill are fergusonite, gadolinite, polyersite, yttria and cyrtolite. The economic interest in these minerals is due to the inesascence of their oxides on being heated. This property makes them available for use as glowers in gas and electric lamps. Thoria, beryllia, yttria, and zirconia are the most useful minerals employed for this purpose. Until the discovery of the deposit at Barringer hill it was practically impossible to get sufficient yttria-bearing minerals to manufacture mantles for electric glow-lamps; but fergusonite and gadolinite, with lesser amounts of cyrtolite, and other minerals containing yttria, occur here in quantities large enough to meet the demand. The Nernst Lamp Co. owns this valuable deposit, but its needs require only the occasional working of the mine. After enough yttria minerals are obtained to supply its wants for several months, the mine is closed. Only a few hundred pounds per year are extracted.

The geologic island in which Barringer hill is situated is interspersed with other mounds and dikes of similar appearance, which have been considerably prospected, without much success. Mr. Hess states that as these rare-earth minerals constitute only a small fraction of one per cent of the total mass, commercially large amounts may exist in a dike and not be exposed at the outerop. He suggests that cracks which generally surround the nuclei of the minerals may be utilized in prospecting. In mining the ore of the larger pockets of Barringer hill the hands and faces of the miners have been affected as if by sunburn, due probably to the radio-activity of the minerals.

The Italian State Railways have recently placed orders with various Italian firms for 300,000 reinforced concrete ties, at a price equivalent to $1.50 per tie.
ORE-SCREEN.—No. 889,673. Frank Franz, Burke, Idaho.

The improved endless screen apron comprising a series of sections formed of screens proper and rectangular wooden frames upon which such screens are secured, and cross-bars and parallel chains which said bars connect, the chains being formed of flat links to which the screen-frames are attached, the ends of the frames shunting as shown and described.

GOLD-SAVING APPARATUS.—No. 889,813. Louis Sachse, Los Angeles, California.

An amalgamating box provided with a detachable mercury container roller bearings entirely inside said container, a shaft mounted in said bearings, disks on said shaft spaced apart by washers and a nut screwed on said shaft and clamping said disks and washers.

An ore roasting furnace having a hearth formed in two substantially parallel stretches the adjacent edges of which are structurally unseparated, a slot in each of the stretches intermediate of the sides thereof the slot being joined by a curved slot continuation, rabbling devices in the furnace and means projecting through the slots to effect their travel.

TUNNEL-DRIVING MACHINE.—No. 891,473. George A. Fowler, Georgetown, Colorado.

In a tunnel-driving machine, a car, a block pivotally mounted upon the car so as to swing horizontally in front thereof, thrusting drills carried by the block, and means mounted on the car and on the block for automatically oscillating the drill-block, the said means adapted for alternate contact—the means on the block with the means on the car at each oscillation of the block, means for operating the drills, and means for causing the car to advance in the cutting operation.

STAMP-MILL.—No. 891,497. Francis I. Matthews, Oakland, California.

No. 891,497

In a stamp mill, the combination of a stamp stem, a sleeve within which the stem is turnable, said sleeve having a projecting wrist-pin, means on the stamp stem for retaining the sleeve in a fixed position relative to the stem, a crank and a connecting rod or pitman through which motion is transmitted to reciprocate the stamp stem, hinged arms connected with the pitman, a table carried by said pitman, springs mounted upon the table, tension rods connecting the springs with the hinged arms, and means connecting the outer ends of the hinged arms with the wrist-pin.

The combination, with a mine cage, and its guides; of a frame, slideable stops carried by the said frame and roping, a pair of jaws pivoted at their lower ends to the said frame, slideable stops carried by the said frame and normally holding the upper end portions of the said jaws in engagement with the said lifting-ropes, safety-clutch mechanism for engaging with the said cage guides operatively connected with the said stops, and means for sliding the said frame and applying the said clutch mechanism automatically when the cage is detached from the lifting-ropes.

DRY CONCENTRATOR.—No. 891,469. Hemer P. Curtis, Denver, Colorado.

A dry concentrating chute or sluice whose bottom is provided with a series of pockets whose rear portions are open at the bottom to permit the introduction of an air blast from below, the rear portions of the pockets being also open to permit the escape of the air, substantially as described.
Analysis of Underground Work, Golden Horseshoe, Kalgoorlie.

The Chamber of Mines of Western Australia publishes in its *Monthly Journal* an interesting tabular statement of the mining operations at the Golden Horseshoe Estates Co., Ltd., one of the largest of the Kalgoorlie mines, adjoining the properties of the Ivanhoe and the Great Boulder Proprietary. The Company leases 199 acres of mining ground titles to mining claims not being granted in Australia. The reduction plant consists of a 150-stamp mill with cyanide annex. The authorised capital is £1,500,000, all issued. The figures given are for the year ended December 31, 1907.

**Men Employed.**—The average number of men employed per day in the underground workings of the mine is 492, distributed as follows:

<table>
<thead>
<tr>
<th>Activity</th>
<th>Number</th>
</tr>
</thead>
<tbody>
<tr>
<td>Stopping ore</td>
<td>368</td>
</tr>
<tr>
<td>On development work</td>
<td>68</td>
</tr>
<tr>
<td>Repairers</td>
<td>15</td>
</tr>
<tr>
<td>'Mullockers' (ore sorting)</td>
<td>66</td>
</tr>
<tr>
<td>Truckers (transmovers)</td>
<td>15</td>

<td>Shift and trucker bosses</td>
<td>11</td>
</tr>
<tr>
<td>Sundry</td>
<td>21</td>
</tr>
<tr>
<td><strong>Total</strong></td>
<td>492</td>
</tr>
</tbody>
</table>

**Shifts Worked.**—The total number of individual shifts worked, namely, 152,111, is equal to 305 working days of three shifts per day during the year.

*Work Done by 3½-IN. ROCK DRILL MACHINES.*—The total average number of machines in constant use throughout the mine equals 23.1. The following are particulars of the work done in stopes and on development:

**STOPING.**

- Number of holes bored: 68,257
- Average depth per hole bored: 6.92 ft.
- Total distance bored: 98.4 miles
- Average number of feet bored per drill per shift: 22.2
- Tonnage of ore broken: 10.6 tons

**DEVELOPMENT.**

- Machines in use per shift: 5.0
- Drifts: 3,666½ ft.
- Cross-cuts: 826½ ft.
- Passes, raises, and winzes: 1,941 ft.
- Shaft sinking: 117½ ft.

Total footage developed: 6,623½ ft.

**Explosives Used.**—The following are the quantities used during the year:

<table>
<thead>
<tr>
<th>Material</th>
<th>Lb.</th>
<th>Tons</th>
</tr>
</thead>
<tbody>
<tr>
<td>Blasting powder</td>
<td>54</td>
<td>0.024</td>
</tr>
<tr>
<td>Gelignite, 1½ in.</td>
<td>170</td>
<td>75.94</td>
</tr>
<tr>
<td>Gelatine dynamite, 1½ in.</td>
<td>2,100</td>
<td>0.938</td>

<tr>
<td>Blasting gelatine, 1½ in.</td>
<td>64,625</td>
<td>28.583</td>
</tr>
<tr>
<td><strong>Total</strong></td>
<td>254,964</td>
<td>109.494</td>
</tr>
</tbody>
</table>

**Detonators** | 132,175 |
**Coils of fuse** | 30,000 |
**Candles** | 30,601 lb. or 30.63 tons |

**Tools Sharpented.**—During the period under review the following number of drills were sharpened, and picks pointed:

<table>
<thead>
<tr>
<th>Tool</th>
<th>Number</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hand drills</td>
<td>79,234</td>
</tr>
<tr>
<td>Machine drills</td>
<td>327,028</td>
</tr>
<tr>
<td><strong>Total</strong></td>
<td>336,262</td>
</tr>
<tr>
<td>Picks pointed</td>
<td>887</td>
</tr>
</tbody>
</table>

**Timber.**—During the year 778,439½ superficial feet of timber has been used for various purposes underground, comprising the following quantities:

<table>
<thead>
<tr>
<th>Material</th>
<th>Feet</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sawn timber</td>
<td>92,768</td>
</tr>
<tr>
<td>Round timber</td>
<td>612,569</td>
</tr>
<tr>
<td>Split slabs</td>
<td>41,597½</td>
</tr>
<tr>
<td>Oregon</td>
<td>31,516</td>
</tr>
<tr>
<td><strong>Total</strong></td>
<td>778,439½</td>
</tr>
</tbody>
</table>

**Work Done HOUSING at the SHAFTS.**—The following particulars represent the hoisting done by the various cages at the No. 1 and 2 shafts (exclusive of 'mullock' (waste) handled between levels):

<table>
<thead>
<tr>
<th>Cages</th>
<th>Trucks</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ore, Timber, Men.</td>
<td>of</td>
</tr>
<tr>
<td><strong>Total</strong></td>
<td>3,286</td>
</tr>
</tbody>
</table>

**For BROKEN and RAISED.**—247,084 tons of ore have been broken and raised during the year:

<table>
<thead>
<tr>
<th>Tons</th>
</tr>
</thead>
<tbody>
<tr>
<td>From stopes</td>
</tr>
<tr>
<td>From development</td>
</tr>
<tr>
<td><strong>Total</strong></td>
</tr>
</tbody>
</table>

Average tonnage per man per shift (based on the total number of men engaged in the underground departments, namely, 492) = 1.624 tons.

Average tonnage per man per shift (based on the total number of miners actually engaged stopping = 262 men for 309 days, breaking 330,983 tons) = 2.533 tons.

**Publications Received.**

**The City of Anaconda,** an illustrated pamphlet of 40 pages commemorative of the twenty-fifth anniversary of the founding of the city. The booklet contains a history of the camp and a description of its present enterprises and industries.

**Handbook of Nevada Mining Companies.** Compiled by the Todd Information Bureau. Paper, pp. 102. Goldfield News, Goldfield, Nevada. Price $1. For sale by Mining and Scientific Press. The corporate name, capitalization, officers, directors, address, names of claims owned, work done, production, and dividends paid of all the mining companies doing business in Nevada, are fully set forth in this little compendium.
Decisions Relating to Mining.

Specially reported for the Mining and Scientific Press.

LOCATION NOTICE—CONSTRUCTION.

The object of a location notice is to give notice to subsequent locators; and if a location notice is defective, a subsequent locator will be bound where he has actual notice of the prior location, at least so far as such defects are concerned. It is the policy of the law that location notices should receive a liberal construction, to the end of upholding locations made in good faith.

RECORDING LOCATION NOTICE—EFFECT.

The location notice, when recorded, is prima facie evidence of all the facts it is required by the statute to contain, and which are sufficiently set forth therein; and with the affidavit of the locator attached, setting forth the fact that the ground was unoccupied mineral land of the United States at the time of his location, when introduced in evidence in an adverse suit, makes a prima facie case. The notices are prima facie evidence of all the facts required by the statute to be stated, which are, in fact, sufficiently stated in the notice. A mistake in the notice may be corrected by oral evidence. The fact as to whether the work was done, is the principal question, and not its method of proof.

QUIETING TITLE TO MINING CLAIM.

In an action to quiet title to a mining claim in support of an adverse proceeding pending in a land office, a complaint was held sufficient which alleged that the defendant, a prior locator, did not have a valid location; that his claim was never marked nor monumented on the ground so that a boundary could be distinctly traced; that the surface boundaries of the claim were never marked by any substantial posts projecting four feet above the surface, nor were such boundaries marked by substantial stone monuments three feet high. And as against the objection that the complaint showed a deficiency in the entry, it was sufficient, as there averred that the plaintiff in a peaceable and lawful manner explored said premises and discovered and found placer gold.

MINING CLAIM—RIGHT TO ACQUIRE TITLE BECAUSE OF VARIANCE.

Certain persons contracted to purchase mining claims which had been surveyed and monuments erected, and for which patents had been issued; but a variance was discovered between the ground conveyed by the patents and the ground intended to be denounced. The purchasers were not stopped, because of the contract of purchase, from denouncing claims covering the territory intended to be included by the vendors in their claims, and from acquiring title to the property adversely to the vendors.

WORKING MINES—INJURY TO SURFACE.

Where the evidence failed to show that the owner of the minerals in working the mines under a reserved right caused or contributed to the injury to the surface, it is said to be immaterial whether the owner of the surface was entitled as an absolute right to subjacent and lateral support to the surface, or whether, having purchased subject to the reservation in favor of the owner of the mineral rights, he had no right to complain of any injury or disturbance, except such as resulted from the want of ordinary care in the conduct of mining operation necessary to prospect for and extract ore.

Knipe v. Anaconda Copper Mining Co., (Mont.) 95 Pac. 128, April, ’08.

Supplying Power for Use in Building the Los Angeles Aqueduct.

Probably no greater feat of hydraulic engineering has been attempted in this country than the project for securing for the city of Los Angeles, California, a water supply from the snow-fed Owens river and its tributaries by means of a 215-mile aqueduct which will bring 400 cu. ft. of pure snow water per second into the city. In building a work of such magnitude it necessarily followed that the question of adequate cheap power to use in excavating, tunneling, and the like assumed prime importance. The large cost of power generated by steam at all points on the line necessitated the adoption of electricity as the motive power. Current is to be furnished eventually from hydro-electric plants built along the line of the aqueduct. The chief source of electrical energy at first will be from the mains of the Edison Company, whose high voltage transmission lines extend to the city of Los Angeles from the Kern River Hydro Electric Plant. In many respects the Kern river power-development is unique. It is claimed to be the largest hydro-electric plant west of the mountains. The transmission line of 117 miles is one of the longest in the world. The pressure of 75,000 volts over such a length of cable is one of the highest ever attempted. The conduit which leads to the pressure-main is the longest underground tunnel system now in use for such a purpose. The concrete-encased penstock, from which the supply will come, tapering gradually to increase the force of the water at the power house, is said to be the first of its kind ever placed in service. The four big wheels were built by Allis-Chalmers Company, of Milwaukee, and have each a capacity of 10,750 hp. at full nozzle-opening, and a speed of 250 r. p. m., when operating under a net effective head of 855 ft. In addition to the main turbines there are two ejector-turbines, also of Allis-Chalmers design, each with a capacity of 450 hp. and an output speed of 450 r. p. m. The Ericsson plant, of the impulse type, with hand-adjustable needles and governor-operated deflecting nozzles. Each unit has two runners, one on either end of the generator shaft. The interchangeable buckets are made of non-corrosive phosphor-bronze and are attached to the cast-steel discs bolted to the flanged ends of the generator shaft. The nozzles are provided with hand-adjustable needles and arranged so as to be deflected by the governor automatically, or by a hand-regulating device. By deflecting the jet, instead of regulating its discharge by adjusting the needle with the governor, it is possible to secure a constant velocity of water in the pipe-line, as well as a constant discharge of water into the tail-race, even when the plant is operating with heavy fluctuations of load. The Kern river installation of the Edison Company costs but little, and the power developments owned by this concern, in addition to six or seven steam plants situated within a radius of 200 miles, all of which will operate in synchro-nization. A portion of the output of this plant is disposed of along the line to Los Angeles. A considerable amount of the power will also be utilized in the city of Santa Barbara. The demand for power in Los Angeles, Santa Barbara, and San Luis Obispo counties far exceeds the supply, and the output from this station helps to satisfy the general requirements rather than being devoted to any specific purpose. The Edison Company contemplates the building of plants Nos. 2, 3, and 4 on the Kern river, which will aggregate over 100,000 hp. in addition to the output of the present station.

Engineering Societies.

The Canadian Mining Institute has published a provisional program for the excursion at the time of the visit of the British and European delegates. The party will start from Quebec on August 24 and stop at Sydney, St. Albans, Sherbrooke, Montreal, Toronto, Niagara Falls, Cobalt, Frank, Water Power developments owned by this concern, to return to Quebec on October 1.
Prizes for Photographs of Wire-Rope Tramways.

The Trenton Iron Co., with a keen sense of the stimulating effect of competition, has turned this to good account as a means for extending the influence of the firm and for enlisting the best kind of cooperation in advertising, through an offer of substantial rewards for photographs of plant in operation, which this concern had designed and erected. The prizes to be won are as follows:

$25.00 For most striking picture of a wire-rope tramway of the Bleichert system showing carriers in transit; or best picture showing carriers in transit on a long span across a river or ravine; or best picture of self-dumping bucket in act of discharging; or best picture of cable hoist conveyor or cableway equipped with patent locked wire track cable. Above to be from negative not less than 8"x10".

$20.00 For ditto from negative not less than 6½"x8½".

$15.00 For ditto from negative not less than 4"x5".

$20.00 For next best picture as above from negative not less than 8"x10".

$15.00 For next best ditto from negative not less than 6½"x8½".

$10.00 For next best ditto from negative not less than 4"x5".

$25.00 For best picture of leading terminal showing carrier in act of being attached to traction rope; or best picture showing carrier with overhead grip attached to traction rope in act of passing around sheave at angle or terminal station; or best picture of station showing bucket in act of being transferred to surface car; or best picture of line crossing a public road of any kind, showing guard net. Above to be from negative not less than 8"x10".

$20.00 For ditto from negative not less than 6½"x8½".

$15.00 For ditto from negative not less than 4"x5".

$20.00 For next best picture as above from negative not less than 8"x10".

$15.00 For ditto from negative not less than 6½"x8½".

$10.00 For ditto from negative not less than 4"x5".

10 prizes of $5.00 each will be awarded for pictures that call for honorable mention, such negatives to become the property of The Trenton Iron Company.

Photographs must show clearly the above-mentioned features of the tramway installation, and be suitable for reproduction in half-tone plates; otherwise they will not be considered. Pictures or negatives not receiving awards will be returned if postage accompanies them. No picture will be considered that has been used heretofore in any way by The Trenton Iron Co. Only one award will be made in each case for best and one for second best, the amount of the award being in accordance with the size of the negative as stated. The merits of the different pictures will be decided by ballot of a committee of five persons to be appointed by the president of The Trenton Iron Co., who will be one of the five and chairman of the committee. Negatives of the photographs winning prizes will become the property of the Trenton Iron Co., and the prizes will be paid upon receipt of these negatives in good condition. Awards will be made October 15, 1908, and photographs or pictures must be entered on or before that date. All photographs or pictures presented for competition, and correspondence, should be addressed to The Trenton Iron Company, Trenton, N. J., and marked "For Prize Competition."

Catalogues Received.

The Sullivan Machinery Co., Chicago, has issued Bulletin No. 602, describing its line of hammer-drills.

The Bristol Co., Waterbury, Conn., has issued bulletin No. 92, describing its line of recording thermometers.

The Jackson Drill & Mfg. Co., New York, has issued bulletin No. 18, describing its line of hand-power rock drills.

The Consolidated Tramway Co., Roanoke, Virginia, has issued a pamphlet describing its system of aerial and motor tramways.

The Jeffreys Mfg. Co., Columbus, Ohio, has issued catalogue 26, describing and illustrating its centrifugal fan as used for mine ventilation.

The C. O. Bartlett & Snow Co., Cleveland, Ohio, has issued catalogue No. 36, the subject being paint manufacturing machinery.

The Joshua Henry Iron Works, San Francisco, has issued bulletin No. 113, descriptive of stamp-mills with triple and quadruple discharge mortars.

The Brown Hoisting Machinery Co., Cleveland, Ohio, has issued catalogue O, illustrating and describing its line of machinery used in the manufacture of gas and coke.

The Vulcan Iron Works, Wilkes-Barre, Pa., has issued a series of attractive sheets giving complete information relative to the different classes of locomotives manufactured by it.

Commercial Paragraphs.

Hampson & Fielding, Denver, have recently incorporated under the title of The Hampson & Fielding Engineering Company.

Ralph C. Nowland, formerly with S. W. Mudd, of Los Angeles, has opened an office as mining engineer at Salt Lake City.

C. F. Nourse, civil and mining engineer, who is at present in Russia, announces the removal of his office to 614 Crocker Bldg., San Francisco.

The Denver Engineering Works announces that it has opened a district office in the Phelps Dodge Bldg., El Paso, Texas. L. G. F. Biggs is in charge.

The Deister Concentrator Co., Fort Wayne, Indiana, has recently received an order for 70 No. 3 concentrating tables from Goldfield Co., Mines Company.

The T. B. Ingersoll Machinery Co., of Salt Lake, recently sold to the Boston Con. Copper Co., a Leyden two-stage air-compressor for that company's Bingham mines.

The A. Van der Naal's School of Practical Engineering graduated this year 29 students in their mining, metallurgy, and assaying courses. The school has been in existence 44 years.

The Lima Locomotive & Machine Works has recently shipped two 50-ton Shay locomotives for use on the Mexican Milling & Transportation Co.'s railroad in the Guanajuato district, Mexico.

W. G. Nichols, formerly assistant superintendent of the Taylor Iron & Steel Co., is now superintendent of the manganese steel department of the American Brake Shoe & Foundry Co., Chicago.

The Cutler Hammer Mfg. Co., of Milwaukee, announces that Otis Squires, 111 New Montgomery street, San Francisco, will represent it on the Pacific Coast. A large stock of Cutler-Hammer controllers will be carried in stock, in surging prompt deliveries.

George W. Myers, San Francisco representative of the Chrome Steel Works, Chrome, N. J., has recently returned from a trip to Alaska, the Boundary and Kootenay districts of British Columbia, and the Coeur d'Alene and reports that he secured a large number of orders.

The Nevada Eng. Works, Reno, has recently shipped a 6-hp. hoist to the Harris M. & M. Co., Jumbo; a 15-hp. hoist to the Maruma Con. L. & M. Co., Seven Troughs; and a 50-ton Lodge gas smelter to the Searchlight Santa Barbara Mining Company.

L. S. Pierce, of Denver, recently shipped to the Western Mines Supply Co., Butte, Mont., to Kearns, Holland & McRae, Nogales, Ariz., and to the Advance Mines, Aetna, Cal., each, one of his 17 by 24 in. silver plated machines; to the Beaver Creek M. & M. Co., Hatley, Idaho, one 22 by 24 in. machine; to C. J. Seymour Baker, Kensington, London, one 10 by 24 in. machine; and to Fairbanks, Morse & Co., at Spokane, Wash., one 27 by 24 in. machine.
CONSOLIDATION OF LAVA, according to Scrope, as appears in citations by Hirram W. Hixon in a letter published in our last issue, is due primarily to escape of occluded gases. This conception originated before 1824, when Scrope published his 'Considerations on Volcanoes.' He merely refers to it for the sake of accentuating the claim that occlusion of gases in large quantities causes "liquidity of the mass." The revival of this old conception is useful. There has been too much stress laid upon cooling of lavas as a means of consolidation. In fact, contact-metamorphism from high temperature is not by any means as common as might be expected along dike-walls; neither has there been the shrinkage which would result from solidification through mere abstraction of heat. Many lavas have manifestly 'set,' after the manner of cement, through the sudden development throughout the mass of interlacing crystals, without reduction of volume, and the elimination of gases may facilitate such crystallization. Angelo Helfprin had recourse to this theory of the earlier geologists to explain the progressive solidification of lava when the great monolithic plug was driven like an obelisk out of the crater of Mont Pelé to a height of 800 feet. Incidentally the ‘set’ did not occur under pressure, and the heat was perhaps dissipated too rapidly to produce a coherent rock. Though it may be working a mere analogy rather hard, we might suggest that as cement needs to set under water to prevent weakness, so lava needs to set under pressure and without too rapid loss of heat to yield such rocks as we actually find filling dikes in the earth. It is evident that such quantities of gas must have evolved from consolidating magmas as to invalidate estimates based on gases in volcanic rocks accessible at the earth’s surface.

LOCAL SECTIONS of the Mining and Metallurgical Society of America are provided for by rules recently approved and issued as Bulletin No. 2. For such local organizations an actual membership of five is required in a convenient area within which reside ten members of the Society. Papers read and discussed are subject to previous acceptance by the council, so that the local associations do not possess any independence or jurisdiction except as members of the central body. They become merely an extension of the field of activity of the Society, stimulating discussion through personal contact. The friction between minds is provocative of new and vigorous thought. This is such a trite statement as to seem almost superfluous, yet it is a remarkable fact that only a few of the technical and learned societies of America have been so deeply impressed with the truth and value of it as to include in their system of organization any provision for associating the
scattered members in nuclei where effective cooperation may be possible. An institution pretending to be national and representative without branches is very like a head without members. On the Martain principle, so lucidly but not alluringly expounded by Mr. H. G. Wells, the memberless head may direct a wonderful and efficient mechanism, but in effect the disproportion between the treasures of wisdom and knowledge which the engineering societies bring to light by their present methods compared to what might be called forth through the direction of a large number of vigorously working associations of members, is as great as that between the practical influence on the world’s work of the Comtian philosophy and of the omnipresent Standard Oil Company. We do not bring these into juxtaposition because of any inherent relation between them, but as a striking example of widely differing degrees of success. An institution to advance the interests of a profession, however, must be so far Comtian, and to that extent imitative of the spirit reflected from the Standard Oil Company in all of its manifestations, as to recognize in man and the world the only two positive and knowable data. It is not for us to point out the different kinds of supreme authority deducible from the evidence in the very divergent examples chosen, but the system which makes men everywhere consciously and acceptably part of a great moving mechanism is both giving and receiving the vital principle of growth.

**Bullion Accumulation in San Francisco.**

SECRETARY CORTELYOU has had a new inspiration. This one has evidently come from a source whence shines a brighter and clearer light. About the kalends of June an order issued to suspend payment for bullion on the Pacific Coast in New York exchange. Uncle Sam’s ‘strong-box’ in San Francisco contained $300,000,000 in coin, and it kept piling up. Nobody wanted much of the metal itself, so long as he could get paper representing it. That was good enough for the people. So the Secretary of the Treasury sought a remedy for the accumulation. But the remedy failed to work. In the first place, Seattle insisted on discrimination in her favor, claiming that the stream of yellow metal from Alaska would pass on to San Francisco if depositors were required to take out their coin. Influence was strong enough to relieve the United States Assay Office in Seattle from the order effective on June 10. Such favoritism was of course undemocratic, and whether it worked advantageously for Seattle or not, it manifestly was not molded after that pattern of fair-play and equal opportunity, for which the Administration has insistently striven to build up a reputation. As a matter of fact it did inure materially to the benefit of the Seattle banks, enabling them to control large amounts of New York exchange, which has for a considerable period commanded a high premium on this Coast. They could thus offer advantages to correspondents sufficient to attract an undue share of the bullion offered at Pacific tide-water, and it made them a controlling factor in the exchange market of San Francisco. The tendency of coin and bullion to accumulate in the sub-treasury at San Francisco was not lessened, and apart from the operation of the separate rule for Seattle, the order to pay in coin would not have produced such an effect. The specie would promptly have gone to the banks for deposit, and thence all that was not required for circulation and surplus reserve would necessarily have returned to the sub-treasury in exchange for certificates of deposit. If the vaults are over-crowded, or—may we be pardoned the indiscretion of whispering it!—if this gold and silver be deemed safer at a point more remote from Pacific waters, one way only is available to get it there, namely, to charter a special train, as in a former instance, and send it under guard across the continent. By reason of a quite superfluous order, further bungled by an unjust discrimination, much inconvenience and trouble have been caused. Some elementary lessons in exchange have also been accentuated, which ought to have been understood well enough in Washington to have prevented interference with the normal currents of business by the adoption of a regulation in June only to be forced to recall it hastily in July.

**The Mine-Warrant for Initial Capital Expenditure.**

THE article in our issue of last week by Mr. Mark L. Requa on the ‘Experimental Mill of the Nevada Consolidated Copper Company’ at Ely, Nevada, is a notable contribution to the subject of adequate preliminary study of an ore deposit before plunging into the expense of installing permanent plant. The course pursued was so logical and simple that it would not seem remarkable except for the fact that the simple and obviously logical procedure to ensure safety is exactly what most corporations usually neglect. A speculative feature is inseparable from a mining venture. For that matter, there is a large element of uncertainty in all industrial enterprise. Financial conditions and variations in the market for raw materials and finished products, introduce risk into every kind of human endeavor. The cost of a manufacturing plant is expected to be returned to the investor, with profits, out of earnings dependent upon favorable conditions of demand for years to come. The comfortable paper manufacturer in New England, for example, need not purchase a Western mine to endanger the security of his capital. There are embarrassing difficulties enough in the provision of pulp-wood, and rags, and esparto, at prices which will assure him a strategic position in the hotly contested fight for commercial success. Thoreau once said, “We sit as many risks as we run.” To think of the manufacturer as shielded from danger, and of the miner as a soldier of fortune exposed to the peculiar perils of a wild frontier of the money-getting world, is to insist on rating the practice of fallacious methods as expressive of a necessity arising out of the nature of the industry itself. It is singular that sane men, long trained in the hard school of commerce and conservative finance, throw their accumulated business-experience to the winds the moment they engage in mining. The customary safeguards, which they would not fail to employ in estimating the chances for a cement works, or a cot-
uniform copper content in the orebody, but incidentally established the utility of churn-drilling for sampling metalliferous ores in place, under normal conditions, where it is found the shingle produced will keep the crevices closed and prevent the fine drillings draining away from the hole. As if this were not enough, the mine was re-sampled by level on a large scale, as explained by Mr. Requa, the samples being actually tested in the experimental concentrating mill erected for this purpose. On the 200-foot level the sample so milled represented 186 pounds of ore per linear foot of workings; on the 300-foot level 225 pounds; and on the 500-foot level 564 pounds. A total of 375,847 tons of ore was milled and a saving of 75 per cent of the copper was demonstrated.

Chance of failure is eliminated by such thorough preliminary study. The mining risk in this case has been a progressively decreasing one. The highest risk was taken by the man who sunk the first prospect-hole. Each advance in development warranted the next expenditure, the warrant becoming surer at each successive stage. The final result is a basis for a safe investment of five or six million dollars. The principles illustrated by this example are equally applicable to enterprises of lesser magnitude. A great many failures in mining are due to insufficient development of ore reserves, not to final deterioration of the deposit. If a mine has reserves capable of supplying the reduction plant with ore for only a brief period, and the development during that period should prove unproductive, the company must face a cessation of output while expending money from the reserve fund or fresh additions to capital or it must drop the enterprise. Disaster of this kind has overwhelmed many companies which might have enjoyed long prosperity if ample ore had been developed before indulging in costly equipment. It is but another instance of the wisdom of the rule to make haste slowly. The eagerness to pay dividends, the pressure to compel an engineer to appraise the geological indications, to sanction immediate production, to order smelting works by telegraph, and ship stamp-mills by express, is the sort of folly which has so often brought disrepute upon mining, and substituted emotional insanity for business judgment in the conduct of mining operations. Mr. Requa's article, showing how the thing ought to be done, should certainly encourage the profession and the general public to insist upon conservatism in the great field of metal-production as in all other departments of industry which are supposed to constitute part of the work of a rational world.

The evident conclusion from the example set is that the ore reserves should demonstrate the possibility of recovery of the requisite capital-expenditure. Such a rule would not appeal to the average man with a mine to sell; it is, of course, hateful to the adventurer; but it means safety to the investor, and insistence upon its observance would improve the tone of the metal-mining world as a whole. It would impart to it that sort of stability and healthy expansion which characterizes the development of our coal resources.
Personal.

Henry Bratton is at Nome.

M. L. Riqua has gone to Nevada.

S. W. Eccles is on his way to Alaska.

F. W. Bradley is near Valdez, Alaska.

F. W. Oldfield is in northern California.

Charles Jamin was in Los Angeles recently.

R. B. Woolley has gone to Honduras and Nicaragua.

Tom C. Woodworth, of Ocampo, Chihuahua, Mexico, is at Denver.

E. C. Mudge is on the west coast of Mexico, near Manzanillo.

F. L. Bosqui has returned from Los Angeles and gone to Goldfield, Nevada.

J. C. Gwillyam, of the Königstuhl School of Mining, is at Conrad, British Columbia.

J. W. Bryant, representing the Tyee smelter, is at White Horse, in the Yukon Territory.

Arnold Berek has been in San Francisco, but has returned to Nevada City, California.

H. J. Muesz has been appointed superintendent of the App mine, at Jamestown, California.

T. Lane Carter, of Johannesburg, is to take a vacation and visit London and the United States.

E. E. Carter has been appointed manager of the Gold Hill & Iowa mines at Quartzburg, Idaho.

Donnyel Foster Hewett has been in San Francisco, and has returned to Nevada City, California.

R. F. Jones is superintendent of the Arctic Chief copper mine, near White Horse, in the Yukon Territory.

J. H. Mackenzie, general manager of the Goldfield Consolidated Mines Co., was in San Francisco this week.

J. Volney Lewis is in northern New Jersey on professional work, where he will be for about two months.

E. A. Haggart, of Los Angeles, was in San Francisco this week. He has recently returned from Sonora, Mexico.

Lloyd B. Smith, instructor in the Pennsylvania State College School of Mines, has accepted a position with Spurr & Cox, Incorporated.

W. W. Mehn has been appointed consulting engineer and general manager for the Eckstein’s Central Administration group of mines at Johannesburg, South Africa.

J. E. Sperry, of the firm of Spurr & Cox, assisted by J. H. Farrell, W. D. Blackburn, and Lloyd B. Smith, is making a complete topographic and geologic survey of the properties of the Helvetia Copper Co., near Tucson, Arizona.

Book Review.

Mr. Rickard has taken the correct and perfectly defensible position that mastery of technique is essential for expression, but he is no hide-bound purist who insists upon reeling off impeccable rhetoric according to unyielding academic rule. He is too full of the warm blood of action to fetter himself or others in that way. Yet we must have rules; there must be known and accessible authority imposing discipline and decorum or we lose that incisiveness which makes speech effective. Mr. Rickard stands for progress, so he lays down rules with the saving clause, “no man can apply a rule intelligently until he understands when to disregard it.” The purpose of the book is to give substantial help on the mechanics of style and composition. The usage current among the best writers with reference to abbreviations; the function of the hyphen; the danger of augmentatives that weaken; the good manners of titles; the correct relations of pronoun to subject; discriminative punctuation; and how to economize the mental effort of the reader; are some of the matters elucidated. It is a handy little volume; bristling with information and stimulus; and a good friend to have at one’s elbow when in trouble over some difficulty of expression.

Publications Received.

Tests of Concrete and Re-enforced Concrete Columns. Series of 1907. A. N. Talbot. Bulletin No. 19 of the University of Illinois Engineering Experiment Station.

General Mining News.

MINEING.

ALASKA.
The management of the Tacoma smelter will in the future pay the miners of Seward Peninsula 60% of the assay value of all quartz ore at the time when the ore is purchased, and the remainder on receipt of the smelter returns. This will be of great benefit to the mining industry and will facilitate the development of more mines.—The Nome Mining Co. has started its big dredge on the Bourbon creek, near Nome. It is claimed that this is the largest dredge north of Vancouver. The hull is 109 by 40 ft. and is equipped with seven electric motors. There are 67 buckets with a capacity of nine cubic feet each, the cutting edge being made of manganese steel. The dredge will dig 40 ft. below the water line, and the water can be held ten feet below the surface, making the total depth to which digging is possible, 50 ft.—The Blue Goose Mining Co. has resumed operations at its property near Nome. The machinery for the new dredge to be erected by J. P. Pearson on Salmon river has arrived and is now being installed.

ARIZONA.

GILA COUNTY.
The King Trail Development Co. has taken a two-year bond and lease, with option to purchase on the Globe & Pinto Mining Co.'s claims, two miles north of Bellevue. The property comprises 14 claims and has been passed upon by mining experts, who class it among the best copper prospects. In one shaft 150 ft. deep, a good grade of sulphide ore is exposed and in another shaft 108 ft. deep there is a 67-ft. cross-cut ending in a vein of sulphide ore not entirely cut.

MOHAVE COUNTY.
A carload shipment of ore from the Connelly lease, on the Flores mine, was made last week.—A station has been cut on the 500-ft. level of the Victor mine and a cross-cut started toward the vein. The work of enlarging the shaft of the Gem mine, at Corbet, is progressing rapidly. A number of carloads of timber have arrived and are being put in place.—A contract has been let for a 400-ft. adit at the Blue Lode mine, at Layne Springs.—Charles Metcalfe has let a contract to Burke & McDermirfor the assessment work on his Great Eastern group, in the Wallapai Min. district. Work has been started.—The Arizona Southwestern Copper Co. has struck a large inflow of water in its shaft at a depth of 270 ft. When the 200-ft. level is reached a cross-cut will be started and a larger pump put in.

SANTA CRUZ COUNTY.
The incline shaft at the Morning Glory copper mine, in the Harshaw district, is down 140 ft. The vein at that depth is a little more than six feet wide.—Work was commenced this week by the Arizona-Pittsburg M. & S. Co. prospecting the Santa Rita No. 2 group of claims, situated on the Veta Grande, in the Wrightson district.

YUMA COUNTY.
The Cunningham Pass Copper Co., which recently made a $6,000 payment on the $30,000 purchase price of a group of four claims, is starting a new working shaft on the great vein, which can be traced the entire length of the claims. Holing machinery will be installed and development rushed with all possible speed. The Company now has 52 men at work on the Boone claims, a short distance from the Josephi purchase, and has that property developed so that regular ore shipment can be made from it in future.—The Castle Copper Co. is building a road which will be completed in a few days, over which the new hoist and compressor will be hauled to its property. R. H. Burnmister, of Phoenix, is interested.

CALIFORNIA.

CALAVERAS COUNTY.
A pocket of rich gold ore was recently uncovered in the Utica mine, at Angel's Camp.—A large dredge is to be started on the rich tailing in Chile gulch. A company, headed by John A. Banton, of Coalinga, has purchased the Green Mountain property near Mokelumne Hill. The Hamby mine, three miles from Mokelumne Hill, is building two dwelling houses, repairing its 20-stamp mill, and getting things in readiness for operation when more water is available.—The Deep Gulch mine has recently started a force of men sinking a winze at the end of its adit.—The North Star mine was closed down last week because of lack of water. It is believed that work will soon be resumed at the Glauira mine. A contract for 5000 ft. of timber has recently been given to Albert Ervin, of Mokelumne Hill.

ELKADAO COUNTY.
The Woodside-Eureka Mining Co. has resumed operations at its property, near Georgetown. The Eureka shaft will be unwatered and all ore will be hoisted through it.—The Garden Valley Gold Mining Co., at Greenwood, will reopen at once. New machinery has been ordered and is expected soon.—The Gilbert mine reports a strike of very rich ore. The mine is equipped with a 15-stamp mill but lacks water in sufficient quantity to keep the whole plant going.

NEVADA COUNTY.
(Special Correspondence).—Several large stockholders of the Brunswick G. M. Co. have been at the mine the past week inspecting the property and considering future operations. It is reported that the mine will be sunk, but nothing official has been given out.—L. W. Jefferson, of San Francisco, is inspecting the Dublin mine on Little Deer creek. Capital is being raised to develop the property.—A new tunnel is being driven to intersect the gravel channel at the Snowden Hill mine. It is expected to attain the objective within 200 ft. The channel ranges from 40 to 50 ft. wide. A new road is also under construction from the main road to the mine. Several surface improvements are being made.—Eastern and San Francisco people, represented by Harry S. Abbott, a mining engineer of Goldfield, have bonded the Lecompton mine for $50,000. The Independence and Treadwell claims, adjoining properties, are included in the deal. The work of unwatering the shaft is under way.—Good results are being attained by lessees at the Inkmargue. It is reported that the parent company will resume operations soon.

Grass Valley, July 21.

SAN BERNARDINO COUNTY.
A recent strike in the upper adit of the Biz Chief Co. exposed a large body of ore assaying about $20, in which there is an 18-in. streak that assays $40. This strike was made at a depth of 100 ft. and the ore very strongly resembles the richer specimens found on the surface.—The
MINING TO MANAGER:

The Buckingham mine has suspended operations, caused directly by the breaking of a cam shaft. The ore has not come up to expectations. The Alaska mine resumed operations last week. The new shaft will be unwatered, and when that is completed sinking will be started.

SISKIYOU COUNTY:

The Wright & Fletcher Hydraulic Mining Co., near Greenview, has cleaned up and turned the water out of its ditches. Although it did not make a long run this season, because of a start late, it is understood that the operation yielded some gold in gold. It is very rare that any gold is found in these claims, save gold, but this year a number of gold nuggets were picked up, the largest being worth about $20.

TUOLUMNE COUNTY:

Acting on permission received from the State, to which the Clio mine had reverted because of the failure of the owners to pay the taxes on it, the property was offered for sale recently at public auction. It was secured by C. A. Belli, of the First National Bank, for $7817.99 for clients. Of this amount $7191.55 is for actual delinquent taxes, with added penalties and costs, and $626.14 interest on a mortgage held by one of the above-mentioned persons. It is reported that a large vein of free-gold ore has recently been uncovered in the Oakland mine, above Columbia.

COLORADO:

CLEAR CREEK COUNTY:

(Special Correspondence)—The first shipment from the strike recently made in the breast of the Scapler adit, brought a settlement of 397 oz. silver per ton. The orebody is from 2 to 3 ft. wide, 8 in. of which is high grade. This is one of the richest discoveries made in some months on Democrat Mtn. The heading of the adit is now nearing the rich mineral zone of the Sunburst. J. Bowen has resumed work on his lease on the Sunburst, and is carrying a stope on a streak of ore that is from 12 to 18 in. wide. Shipments will be started at an early date. It is reported that a large vein of free-gold ore has recently been uncovered in the Oakland mine, above Columbia.

HINSDALE COUNTY:

The Sterling group of claims, near the San Juan county line, has been purchased by F. J. Piennar. He has advertised for contracts to drive an adit on the Nellie G. claim and will thoroughly develop the group.

SAN JUAN COUNTY:

Frank Pratt will begin work at once on the Excelsior property on Boulder Mtn. He has already sent supplies to the camp. The Empire Zinc Co. has taken over the mining claims owned by A. S. Sturgis, near Animas Forks, and has started a number of new buildings. A new plant of machinery is contemplated.

TELLER COUNTY:

The production of the Cripple Creek district for the first six months of 1908 was $7,972,247, which is considerably larger than the corresponding production for 1907. The largest monthly output during the half year was in March.

IDAHO:

The Bear Creek Milling Co. has recently purchased a 20-ton mill and expects to install an electric power plant at a later date. The Golden Sunbeam, at Sunbeam, is working hard and many in the mine are busy. The Dowey has recently cut a vein of galena ore six inches thick at a depth of only three feet. Six men are to be worked at the Red Cloud group of mines, on Deer creek.
IDAHO COUNTY.
The work of moving the 5-stamp mill from its location cast of Elk City to the South Fork mine, on the Clearwater, is now in progress. The sawmill and other equipment ordered some time ago is now on the ground, and the company expects to be milling ore not later than the first of September. — It is reported that recent changes in the treatment in the Butte & Orogrande mill, at Orogrande, have materially reduced the cost and increased the extraction, and that as a result large quantities of ore will now be treated.

NEZ PERCE COUNTY.
(Special Correspondence.)—A crew of 15 men is digging ditches and building flume for the Orogrande Placer Mining Co., which expects to install a Rubel elevator this season and get a six-weeks' run. — A Rubel elevator is now being installed by the Rhoades Creek Placer Mining Co. and will be in operation in 10 days. This type of gold-saver is best adapted to the flat bottoms of the Pierce City district. The big Riden dredge of the Idaho Co. is working day and night. A duplicate, of the one now working, will shortly be ready for operation. Pierce City, July 21.

SHOSHONE COUNTY.
(Special Correspondence.)—The Golden Chest mine and mill will both be started at an early date. It is now four years since the mill was operated and a considerable amount of repair work will be necessary to get it in shape. The mill has 20 stamps with a capacity of about 50 tons per day, but it is the intention of the company to replace this with 24 stamps. — Spacing.—F. F. Pierce and C. C. Coeur D'Alene North Fork Mining Co., which recently took a lease on the property of the Monarch Mining Co., makes the announcement that by the beginning of the year, and provided that the Idaho Northern railroad is completed, shipments at the rate of 200 tons per day will be made from the property. Active development work is to commence about August 1 and will be devoted toward the completion of the raise between the lower and the upper workings. It is estimated that there is already about 30,000 tons of ore blocked out in the upper workings. The property is equipped with a 100-ton mill. The ore will be shipped to the Pueblo smelter, in Colorado. —Work is about to resumed on the property of the Snow Cliff Mining Co., on the Montana-Idaho divide, near Salooze. It is the intention of the company to drive on the veins to obtain a depth of about 200 ft.—An official announcement has been made to effect that no dividend will be paid this month on the stock of the Snowstorm mine, at Mullan. The company has been shipping at the rate of from 400 to 500 tons per day and the proceeds are said to have been applied toward the payment of certain indebtedness of the company.—A lead of fully 60 ft. in width has been opened up on the property of the Susquehanna Tunnel Mining Co., at Pierce, at a depth of about 400 ft. It is the intention of the company to commence driving to get under the surface showing. A drift to the east of about 600 ft. will give a depth of about 800 ft. on the orchory. Wallace, July 20.

MICHIGAN.
The railroad line will be completed to the Phoenix mill by July 15. The mine will then be able to begin shipments of 300 tons per day. — Work in the north drift of Lake has been suspended. Sinking and driving are being done in the south drift alone. The next station is likely to be at the 400-ft. level. A remarkably rich showing is noted in the south drift. — The Superior Mining Co. started last week cutting down the No. 1 shaft to three-compartment size. No definite date is set for the beginning of production. Possibly this is somewhat dependent upon the settlement of the Osceola-Calumet & Hecla litigation. — No. 1 shaft of the Alliance had a depth of staked out 300 ft., and continues to go down at a good rate. The nature of the rock now coming from this shaft is such that the Allozzen apparently will not make the showing it did a year or two ago. The mineralization is showing no improvement of fate. — Calumet & Hecla is removing the pumps and other machinery from the Keweenaw county explorations to Calumet, indicating a determination to abandon these explorations indefinitely. — Michigan has discontinued work on the new stamp mill in order to conserve funds and thus meet the necessary assessed taxes. Another new mill may have been completed this fall if the work was pushed. Michigan will continue to use two heads of the Atlantic mill. — The Franklin Junior is shipping the last of the amygdaloid stock rock in opening the Pendarve shaft. The sinking of a shaft has been started to connect with the upralse from the 23rd-level cross-cut of No. 1 shaft. Stopping has been made in progress on several levels and a fair grade of stamp work is being handled, though little mass is obtained. — Conglomerate is growing leaner with depth. Franklin Junior's present production is about 15 cars of conglomerate and five of amygdaloid. — James Chynoweth has been elected president and general manager of the Hermima Mining Co. The smelter has been completed and will be blown in early next month. The completion of the Canadian Pacific branch will make direct shipments to the smelter possible.

NEVADA.

ESMERALDA COUNTY.
The Goldfield Syndicate Mining Co., which owns a one-half interest in the Rogers-Syndicate lease, has purchased the Nevada Rockland, one of the old mines in northern Esmeralda county near the old camp of Ediee, Cal. The property was equipped with a mill by Eastern people, who worked it last year on a bond. — The Daisy syndicate, at Diamondfield, will resume shipments this week, having 100 tons of gold ore in the bins. A full force of men are at work. — The Goldfield Con. Mines Co. and the Combination Fraction Mining Co. have entered into an agreement by which the boundary between the two properties will be the vertical plane through the surface lines. — A contract has been let to sink the Hazel Goldfield shaft, on the Laguna, from the 450 to the 550-ft. point. The contract price is $35 per ton. If the work is done within 30 days a bonus of $3.33 per ton will be given. — The work of unwatering the Clement shaft on the Goldfield Con. Mines Co.'s estate began this week, and as soon as it can be remodeled and enlarged, sinking with three shifts will begin. — Frank Hervey Pettingill, of Colorado Springs, Colo., has purchased control of the Jack Bell lease on the Queen Bethania property at Rawhide. — The mines of Goldfield produced during the week ending July 15 a total of 2150 tons estimated to be worth $189,755. During the same period the Tonopah mines produced 4725 tons, of an estimated value of $119,325.

HUMBoldt COUNTY.
Stanfar, Merchant & Reinhart have taken up their option on the Goldbanks Extension, at Goldbanks, and will develop the property. A strike was recently made on the 140-ft. level, assays from which show $270 gold per ton. Thirteen lessees are at work on the Badger and Yellow Dog claims, at Seven Troughs, owned by the Fine Gold Mining Co. and a large tonnage of milling ore is being taken out. The Company is negotiating for a four-stamp milling plant.

LINCOLN COUNTY.
Two carloads of machinery have arrived at Pioche for the Nevada-Dal Mines Corporation. The equipment includes a 40-hp. gasoline engine, an air-compressor, drills, cars, rails, and many minor accessories. The plant will be erected at once and development started. — It is believed that both the Searchlight M. & M. Co. and the Searchlight-Spokane Mining Co. will be in operation by September. — The new Ronge mill plant of the Quintette mine, at Searchlight, was started last week. One shift of 10 men will be employed. — The Philadelphia Searchlight has closed down, the reason not being stated.

Nye COUNTY.
A company of California and Eastern men have pur-
chased the Pactolus mine, about seven miles from Atwood. They propose to equip the mine with modern machinery and start active development. — A settlement has been reached by which the various contestants against the application for patents sought by the Manhattan Consolidated Gold Mines Co. have deeded to that Company all territory demanded, and adverse suits have been withdrawn. It is a settlement of far-reaching importance to the mining interests of Manhattan. — Development work is being pushed in Jim Butler ground through both the Wandering Boy and Stone Cabin shafts, the former being used to open up the acreage in the Fraction No. 1 claim, while from the latter that portion of their property lying immediately south of the Tonopah Co.’s claims is being energetically prospected. No ore is being extracted, all work being confined to the developing and opening up of the ground. — The Homestake King mill, at Rhyolite, will probably be increased to 60 stamps in the near future. This property has developed large orebodies on the 400 and 500-ft. levels which seem to warrant the additional milling capacity. The mill has been in operation but a few days and has been running very satisfactorily. — The Security Reduction Co., owning nine patented claims near Manhattan, is installing a 150-hp. gasoline engine, and in addition to the Oregon gold-fields as a dredging proposition. — An important strike was recently made at the Success group, in the Sumpter district. It consists of four feet of good milling ore and a streak about six inches wide, which will assay very high. — The Gold Hill, in the Granite district, has been leased by Norman T. Berkly, who has already started a force of men at work. Cross-cut No. 2 will be continued to strike the vein, which should be reached within 100 feet.

UTAH.

SUMMIT COUNTY.

The Godiva has been reorganized and will issue stock to the amount of $1,000,000. Work will be under way in a short time. The 900-ft. shaft will be deepened 300 ft., and leases will probably be given on the old mine workings. — The Eagle and Blue Bell mine, which had been idle since last fall, is once more in operation, work having been resumed there last week. For the present most of the work will be carried on by lessees, but later the company will put the old time force upon the pay-roll and commence sending out a heavy tonnage of ore. — Moore & Duncan have been given the contract to sink the first 100 ft. in the new shaft to be started on the Tintic Central Co. ground. The shaft is to be sunk on the Dominion No. 1 claim and will have two compartments and a manway. The contractors are now ready to start sinking, the necessary grading having been completed. — The shipments from the mines of the Tintic for the week ending July 17 amounted to 9040 tons of ore and 100 tons of concentrate. — The work of developing the King William ground, at Eureka, will be started soon. The operations will be carried on through the Eagle and the Blue Bell workings. — As the work of repairing the shaft of the Mammoth Mining Co. is being done below the 1100-ft. level, some of the lessees have again returned to their work in the mine, but no ore is being raised to the surface. The repairing and overhauling of the machinery at the property is completed.

WASHINGTON.

WHITE PINE COUNTY.

The first copper matte from the Steptoe Valley Smelting & Mining Co.’s reduction plant, at Smelter, was turned out Wednesday, July 15. The smelter is not in full blast yet, due to delay in the arrival of some of the missing accessories. The quality and cost of the blister copper are considerably better than was estimated. — An order recently issued at the mines of the Nevada Consolidated prohibits the smoking of cigarettes while on duty, on the ground of the danger from fire and the fact that men who smoke cigarettes are not dependable. — The Giroux Consolidated Mines Co. has closed a five years’ contract with the American Metal Co. for the sale of its copper.

OREGON.

Three carloads of machinery for the Alameda mine were unloaded at Merlin last week, and it is now being put in place. The new plant will have a capacity of 100 tons per day. — The ore cars and track for the electric gold dredge, on Kanes creek, arrived from the foundry recently, and is now being placed in position. As soon as this work is completed the machine will be put in operation. Much interest is manifested in the operations of the machine, as its success or failure will determine the future of the southern...
SNOHOMISH COUNTY.

The Bunker Hill smelter at Ritter, in the Index district, was blown in last week. The plant turns out blister copper and copper matte and has a daily capacity of 75 tons. The Bunker Hill mine and concentrator will furnish half of the capacity of the smelter and customs ore from mines along the Great Northern line in the Cascades and will keep the plant running full blast. The American Mining Co. has opened up a large vein on its property at Silver Lake, on the divide between the Silver Creek and Monte Cristo districts, and building a sled road over which to haul the ore to the railroad at Monte Cristo. The ore is an arsenical iron silver, $21 in gold and $8.40 in copper. Upon completion of the sled road the company will commence shipping to the Bunker Hill smelter, near Index.

STEVENS COUNTY.

(Special Correspondence.)—The mines under development on the east side of Kettle river, near Orient, are steadily improving, and a smelting plant in that neighborhood is expected as a necessity at no distant day. At the Orient the old workings have been temporarily abandoned and a new shaft is being sunk. It is down over 60 ft. in vein matter, which becomes more heavily mineralized as depth increases. The First Thought mine is sending regular shipments of ore to the Northport smelter. The aerial tram, which was out of commission for a few days, is running smoothly. A rumor that this mine had been sold to English and Scotch capitalists for $9,000,000 has been verified. The only thing which gives color to the report is the visit of Alexander Sharp, the manager, to Scotland, his native land,—D. T. Hodnett, superintendent of the Valley Dew M. & M. Co., has reported that the adit, for the development of the extension northward of the First Thought vein, has intersected the vein 50 ft. from the portal, and the ore is about 30 ft.; the vein is about 50 ft. wide, and the ore averages $23 per ton in gold. The mine is about three miles distant from the railway, with half a mile of wagon road to be completed, preparatory to shipping ore, which will be begun as soon as the road is finished.—The Second Thought Gold Mines Co. has been incorporated, with its principal place of business at Orient, Ferry county. The company has taken over the Second Thought group of five claims, which adjoin the First Thought group on the south, and carry the extension southward of the First Thought vein. The group was located ten years ago, but lacked development.—The Trojan mine, on Toulon Mtn., has been opened by an adit 800 ft. long, which tapped the vein at a vertical depth of about 500 feet. The adit passed through vein matter, assaying $136 in gold, before reaching its object. Several fine ore reefs have been developed in a winze which goes down from the end of the adit. The property is owned by the Trojan M. & M. Co., Washington, D. C.—The Gem mine has been incorporated under the corporate name of the Beecher Gold Mining Co. It is situated on Toulon Mtn. and produces ore showing free gold, samples having assayed as high as $90,000 per ton. Work will be started immediately. This property was incorporated as the Judging Mining Co. and incorporated under the same name in the State made a change in the title imperative. The new company has funds on hand sufficient for a year's active work.—A new strike in the Globe mine, on Toulon Mtn., is a vein of ore four feet wide. It was made in a drift, at an estimated depth of 250 ft., on the main adit level. This strike, added to former developments, gives assurance of a payable ore body. A small pan mine has been made in the lower adit on the Paymaster mine, which has added much to the ore in sight in this property. Arrangements have been made for shipping to the railway, at Orient, in transit to the smelters.—A contract has been let and new work has been started on the Trophy mine.—A new strike has been made in a 200-ft. cross-cut adit on the Lene Pine mine, on Deep creek. The adit has intersected a 4-ft. vein of silver-lead ore of commercial value, at a depth of 70 ft. The property is owned by British Columbia people.—A spur, six miles long, will be constructed immediately from the Spokane Falls & Northern railway to the United Copper mine, near Chewelah. A new boiler and two Burleigh drills will be installed, and the ore shipments will be increased to 1000 tons per month. The company will open new levels from the winze at every 50 ft. and thus increase the output of the mine to almost double its present production. The raise to the surface will be completed in August. About 20 men are employed, and eight four-horse teams are engaged haulling ore to the railway. The final settlement has been made on a bond for the purchase of six additional claims.—A vein of asbestos five feet wide is reported to have been discovered eight miles east of Chewelah, which can be traced a distance of 1200 feet.

Chewelah, July 20.

CANADA.

BRITISH COLUMBIA.

It is reported that the directors of the Yunir Gold Mines, Ltd., have decided to spend $39,000 upon improvements at the mine. The rehabilitation of the mill, the reconstruction of the water flume, and the developing of new levels will be undertaken. Horace G. Nichols, Yunir, B. C., is manager.—E. H. Smith, of Spokane, has purchased a controlling interest in the Maud S. and the Maggie claims, which are a short distance south of Forty-nine creek, in the Nelson district. The consideration was $29,000. Two veins on the property cut each other at almost right angles. One bears gold and copper and the other contains free-milling gold ore.—The St. Eugene mine, at Moyie, shipped over 600 tons of concentrate to smelters in West Kootenay last week.—The management of the Aurora Mining Co. is purchasing new machinery to develop the property at Moyie.

Following is the tonnage of ore shipped from and crushed at the mines of Rossland for the week ending July 11, and for the year to date:

**Totals:**

|       | 5640 | 152,257|

The district shipments were: Boundary, 31,417 tons; Slocan-Kootenay, 1932; Rossland, 5,616. Total for the week, 88,900 tons.

ONTARIO.

The output of the Cobalt camp for the first six months of 1905 was 9151 tons as against 6543 tons for the corresponding period of 1907, an increase of 2608 tons. This increase in tonnage does not reflect the actual growth in shipments and value of the output, because of the fact that several of the leading properties have during the year treated lower grade ore and the output of the smelters only high-grade ore and concentrate. Kerr Lake, Conigas, Buffalo, and Cobalt Central shipments now consist wholly of high-grade ore and concentrate, and the smelter returns from these shipments run very much higher per ton than those from the ore shipped by the other mines. The month of July will show a large increase in tonnage over the corresponding month of last year. Thus far the O'Brien has shipped 96 tons, the Nancy Helen 93 tons, the Silver Queen 90 tons, and the Nipissing 63 tons of ore, while four other companies have sent carloads ranging from 26 to 47 tons per car. Cobalt Central has a car ready to ship that will run 25 tons of concentrate and will send a second car the last of the month. The last-named company is installing some additional machinery in its concentrating plant for the purpose of materially increasing its capacity and adding to the economies of operation. The plant is now showing an average saving of 92% of metal values; the changes will increase this average to 96 per cent.
Special Correspondence.

NEW YORK.

During the past week the general tone here has considerably improved, largely attributed to the result of the Denver convention. The betting at Lloyd's on the result of the November elections now stands at 5% to 2 on Taft, and business interests have already begun to discount the result of Bryan's expected defeat. There has, however, been a general improvement abroad, which would naturally be reflected in this market. It is, accordingly, unfair to place too much stress on politics to account for the tone of the market.

There has been more business on the curb-market this week, and while this does not always indicate investment-demand, there has been genuine activity in several stocks, including the Nevada Consolidated and the Mason Valley. The Amseek Mining Co. held its annual meeting in Boston on July 2, when the directors were re-elected. The Company is making a gratifying showing of earnings at the present time, but dividends are not in sight, as new shafts are in progress and a stamp-mill will have to be built; at present the ore is being milled by the Osceola and Tamarack companies. A treasury surplus is being accumulated to meet the cost of this work, and on January 1, 1908, the Company had $14,837 cash on hand.

The present copper quotation seems to be in line with the prospects of a rapid recovery in the price of copper. This metal will always feel the result of an industrial depression longer and more severely than iron and steel, as the latter are being continuously used by going concerns, while copper is consumed more particularly in new installations. During the past year many proposed installations have been held up for want of credits, and when confidence returns, the sudden demand is expected to force the price up to 14c. The export movement is still very heavy, having averaged 2,000,000 lb. daily since January 1. This means that more than two-thirds of the copper produced by the mines of the United States, Canada, and Mexico is being exported. While few of the copper stocks are earning enough money at the present price of the metal to warrant a higher selling price, the outlook is beginning to discount the future, and prices should rise considerably.

The sixth annual report of the International Nickel Co., for the year ended March 31 has been issued. This Company, operating abroad through the Nickel Corporation of London and the Société Minère Caledonienne of Paris has practically a world-wide monopoly. The Company is capitalized at $50,000,000, of which $50,000,000 is preferred stock, and $8,822,661 of common stock. It was organized in 1903, and while it has not paid any dividends on common stock it has spent out of earnings about $5,000,000, in smelting and power plants at Sudbury, Ontario. Originally opened as a copper property, the ore has been developed chiefly for nickel. There are said to be fifteen million tons of ore shown up by diamond drills, which will average 30 ton per gross, or over 15 net. Two years ago the annual consumption of nickel was 4,000,000 lb., but it is now about 20,000,000 lb. Two years ago the net earnings were $300,000 less than last year, so it is evident that the International Nickel Co., by controlling the output, have been able to maintain their earnings even during an off-year.

The last annual report announced net profits of $1,324,742, after deducting expenditures of $1,458,481 for construction, etc., $215,975 for depreciation of plant, $94,351 for exhaustion of minerals, $168,250 for bond-sinking fund. And after making allowances and payments of bond and stock interest, it reported an additional surplus of $700,000. There was then deducted $300,000 more from the surplus for further depreciation of property. These figures seem to indicate an exceedingly prosperous condition of this company. It is controlled by the same men that made millions out of the early Nipissing boom.

LONDON.

Burma Ruby Mines, Ltd.—Wanderer Gold Mine, Rhodesia.

We have heard recently a great deal about the troubles of diamond mining companies, due to the crippled resources of the buyers of ornaments. It is not only diamonds that are in the shade, but all other precious stones as well. The depression in the ruby trade can be gauged by the present position of the Burma Ruby Mines, Ltd. This company was formed nearly 20 years ago by the Rothschilds to work the celebrated deposits in Burma, where the highest quality of rubies and other corundum spinel stones are found. At the time of flotation there was a mad rush for shares, for it was supposed to be one of the most valuable investments possible. The hopes of the company have not borne out these early hopes, and the profits have been much less than expected. The capital was originally $500,000, divided into 250,000 ordinary shares of £1 each, and £100 in founders' shares. The ordinary shares are supposed to receive a dividend of 20% each year, and the surplus profits are then to be divided equally between the ordinary and the founders' shares. Unfortunately this distribution of profits is only theoretical, for the profits have never been sufficient to pay a 20% dividend on the ordinary shares, let alone provide any dividend on the deferred shares. For ten years no dividend at all was paid. From 1898 to 1906-7 dividends varying from 4 to 15% were declared, except in the year 1905-6, when the dividend was passed. For the year ended February 28 last, there was a small balance of profit, but owing to the stockholders' anticipation, the dividend was not declared.

During the first ten years of the company's existence the high rent and royalty payable to the Government were a great drain on profits, and upon several occasions the Government consented to reduce the duties. Also in 1897 the company found it necessary to re-organize its capital in order to write off the considerable losses, and the nominal capital was reduced from $500,000 to $180,000 by cutting down the nominal value and the number of shares. The company has, however, always been able to pay dividends each year, and since 1906 has been paying 4%.

The discoveries of new mines, especially in the last few years, have caused great alarm to the company's share-holders. But it will be noted that the dividends mentioned above were paid on the reduced and not on the original capital. During the last four years over $35,000 has been spent in driving a new tunnel which will serve the double duty of coping with the floods and assisting in the exploration of new ground. The necessity for this drainage-tunnel was made apparent by the extraordinary floods that swept through some years ago. The tunnel is now practically completed.

The ground is worked chiefly by the company, but several parts also are operated by lessees who pay a royalty on their output. The disposal of the company's stones is effected locally and also through London brokers, the amounts disposed of in these two ways being about equal. As regards the present position of the company, it has been found necessary toisNaN the grade of the ore at Selukwe at 56% as compared with the grade of the ore in London during the last nine months. The sales in Burma have not been affected to the same extent, but have diminished by perhaps 25%. What would be the best policy to pursue under the present circumstances is a question that has given the directors great anxiety. It is very undesirable to close down work of this sort in a country like Burma, where the natives have little call to request resources.

We have been informed that the gold mine in the hands of the company is situated in Mashonaland and has already produced $168,250. There is no further news of the mine at the present time.
mining is done by open cut and some by underground workings. Owing to the nature of the rock it is difficult to keep the ore and the barren ground separate, and the average of the ore treated is lower than would otherwise be the case. The ore is crushed in rolls and cyanided. During the twelve months from May 1, 1907, to April 30, 1908, the amount so treated was 190,337 tons, and the extraction was 19,563 fine ounces, which realized £53,291. The working-costs were extremely low, amounting in all to £16,625. Of this, £22,221 was spent in mining and tunnelling, £1,471 in milling, £16,369 in cyaniding, £536 in maintenance of the mine and buildings, and £5,075 in administration, consulting engineers' fees, and so forth. These expenses amount to 6s. 6d. per ton treated. A nominal mining-profit of £21,563 was left, out of which £4870 was spent in development work, £4905 in machinery, and £4932 in sinking a new main shaft. In rendering the accounts these latter expenditures are charged to capital account, and allowance is made for depreciation and mine-development redemption. During the year £2919 was also spent in London office expenses, and the actual balance as it appears in the profit and loss account is only a nominal one. Like most Rhodesian companies, it is overburdened with capital. The shares issued represent £490,000. The purchase-price when the company was opened was £300,000 in fully-paid shares, and in 1902 further property was acquired, the consideration paid shares, bringing up the vendors' consideration to £277,500. In all, £122,500 has been subscribed in cash, of which £36,666 was provided by the British South African Co., £12,500 by the Charterland Goldfields Ltd., and £73,324 by the shareholders in the latter company. Milling commenced in 1902 and has been continuously carried on since. At the present time the plant is capable of treating 2000 tons per week, and last month the output was maintained. The content is very variable. In some places the gold-assays run to as much as 10 or 12 dwt. over a width of 70 ft. The details of production and cost are given fully, and as is usual with the Tarbutt companies, the gold output is given to four places of decimals.

JUNEAU, ALASKA.

Although the season opened nearly a month late, there is a good deal of activity at the Silver Bow mill. The Alaska-Perseverance Mining Co. has 100 stamp mills, 75 foot, treating 550 tons per day. The ore is coming from stopes started from the main level of the Alexander adit, which cuts the lode 1200 ft. deep, on the dip. A stopping of width 15 ft. is being maintained, but the full width of gold-bearing quartz and schist is claimed to be over 80 ft. Seven machine-drills are in use. It is said that 100 more stamps have been ordered and will be erected this summer. John R. Mitchell is superintendent, and he is assisted by David Argall and Byron H. Moore. The Company is controlled in England. Arthur L. Pearse is consulting engineer. The same lode is being exploited in the adjoining property of the Alaska-Juneau Co., controlled by Wernher, Betz & Co., of London. The 30-stamp mill was started for this season on June 25, crushing 150 tons per day. The ore is easily comminuted and does not warrant the use of concentrators. Last year, in 135 days, the length of the season, 19,798 tons were crushed for a yield of $22,093. The yield was $1.12 per ton; the milling cost was 20c. and the mining cost 55c. per ton, so that this is one of the lowest grade vein-gold mines in operation anywhere. The lode-channel is schist, traversed by quartz stringers of varying size, and it is worked in open pits, delivering the broken ore to millholes leading to shafts. About 20% is sorted out. W. P. Lass is superintendent, and Robert A. Kinsle, who is also manager of the Alaska-Treadwell Co., acts as consulting engineer. In the basin below these two mines the gravel deposit formed from the disintegration of the quartz veins is being worked by Emil Kaufman, as lessee from the International Trust Co. of Boston. He has a 5-in. noacle at work, with 1000 ft. of block-rifles, and 3000 ft. of sluice paved with stone. The conditions for hydraulicking are good, but rich spots balance the difficulties. In the Gold Creek canyon, leading from Juneau, is the Elvera mine, which has just been sold and a large first payment made. It is planned to erect a stamp-mill on the Gastineau Channel, near Juneau, and connect it to the mine with a tramway. This mine is controlled by W. Eber and H. M. Behrends, a banker of Juneau.

On Douglas Island, the big mills of the Alaska-Treadwell, Alaska United, and Alaska-Mexican mining companies are all busily at work. The Treadwell has 546 stamps, in two mills, 300 and 240 heads respectively. The deepest workings are on the 1450-ft. level, but there is no stopping below 1250 ft. The maximum width of ore excavated underground is 300 ft., the stopes being 75 ft. along the lode, with 25-ft. pillars to hold the ground. Reserves of ore are estimated at 4,647,743 tons, averaging $2.35, with a total working cost of $1.33. The tailing runs 20 cents per ton. Oil has recently been adopted instead of coal for generating steam and the change has proved very advantageous, the economy during the year being estimated at $110,000. Labor conditions have improved, and the strike declared in March has proved ineffective, all the properties being operated at full capacity. The management is doing everything possible to improve the conditions of living. Each of the married employees has been built, to be rented at a low figure to married couples, it being desired to obtain a permanent population. Experiments in applying cyanidation to re-ground concentrate have proved successful, and a 10-ton plant is being built as the basis for a 100-ton annex. A dam to hold 210,000,000 gallons is now under construction in the mountain basin two miles south of Treadwell. This will prove a valuable auxiliary when water is low in the ditch. Robert A. Kinsie is general superintendent of the four mines belonging to the three companies already mentioned, and E. P. Kennedy is assistant superintendent. At Sitka there is a revival of interest in gold mining, due to the success achieved by the Chichagoff Co., of which Edward de Groff is president. The mine is on Chichagoff island, 60 miles north of Sitka. The mill contains four Hendy triple-discharge mortars, and one Wilby table. Murphy drills are used for stoping. The first work was done in 1905 and since then the mill has yielded $100,500. The mill was erected a year ago. The vein is from 2 to 8 ft. wide, and yields $24 to $29 per ton, with gold to $2.63 for oz. This is a very soft lode. A new vein, longer than the first tunnel, is now being driven. A. M. Angelmoky is superintendent. The extension of this vein is being opened up by W. P. Mills & Co. of Sitka. At the head of Silver Bay, on Baranoff Island, 10 miles from Sitka, are a number of prospects, but not much work is being done. Nicholas Haley is working a promising quartz-vein gold on Bear creek; this is near the Stewart mines, a property controlled by ex-Governor Brady. On Salmon creek, the Lucky Chance Co. has 10 stamps and a tramway, but the mine is idle. H. A. Bauer has driven a tunnel 1400 ft. He is expected soon at Sitka. There is probability of activity in gold mining in this part of Alaska.

MEXICO.

Railroad From Guadalajara to Mazatlan.—Mining Development along the Route.—Water-Power Plants. — Cyanide Treatment Extending.—New Mills in Hostilipapiquillo District.—Carrizo Smelter at Ayutla.

The first spike has been driven in the branch of the Southern Pacific railroad west from Guadalajara by Governor Ahumada of the State of Jalisco. The branch at present starts out from the Orendain station of the Guadalajara branch of the Mexican Central, and the driving of the spike was made the occasion of a feast-day for that part of the country. A special gold spike was furnished, and all the notables of Guadalajara were present; and will may they celebrate the event, for the extension and com-

ROSSLAND, BRITISH COLUMBIA.
Mining Institute Meeting.—Consolidated Mining and Smelting Co.—
Low Costs at Granby.—Results from Leasing System.
Arrangements are being made by a committee of local mining men for the entertainment of a distinguished party that will visit the mines of this district in September. Members of the Canadian Mining Institute and their guests will visit the principal mining districts of Canada early in September and will arrive in British Columbia about the 15th of that month. The guests of the Canadian Mining Institute on this occasion will be fifteen of the leading mining engineers of Great Britain and Europe, who will represent the several affiliated societies while here. For the purpose of entertaining this party the Dominion Government has set aside $10,000, the Province of Ontario $3000, and British Columbia will appropriate $5000 at least. The Governor-in-Council of Canada has offered an interest in the smelting industry, and is ever ready to aid any movement to benefit it. This visit of foreign mining engineers will be a great aid toward inducing foreign capital to invest in the rich mines of this country. At present there are very few mining men on the Continent who have more than a vague idea of mining conditions here, and therefore are not in a position to intelligently direct the investment of capital in this country, but after this party has visited the principal gold, silver, lead, and coal mines of Canada, there will be a group of Continental mining engineers who will have a good idea of mining in this northern land, as far as orebodies, working conditions, and profits are concerned.

The Consolidated Mining & Smelting Co. of Canada is making a good showing in its mining operations this season, when existing conditions are taken into consideration. For nine months of the fiscal year ending June 30, the gross value of the output of the mines at Rossland, Moyie, and Phoenix, and of the smelter at Trail, was $4,178,786, which was $100,000 greater than for the entire year of 1906. A favorable report from this company for the year's work is anticipated.

The mining companies in the Boundary have settled down to earnest work and many little extravagances which were overlooked when copper was at a high price have since been cut off. The Granby and B. C. Copper companies are working steadily and producing a heavy tonnage. It is stated that the Granby is making copper for a fraction over 8¢ per pound, and at the rate of 30,000,000 lb. per annum. The Dominion Copper Co. has just begun shipping its Brooklyn-Stemwinder, Rawhide, and Sunset mines, and has its big furnace treating 650 tons of ore per day, but shipments will be greatly augmented after the new 1200-ft. tramway, from the Idaho to the Stemwinder, is built, and after the two smaller furnaces are equipped with electric feed, which improvements will effect a material saving on each ton of ore handled. No one in this district expects copper to remain at its present abnormally low price for many more months, and when the expected rise does take place the Boundary mines will be in an excellent position to reap the benefit. As an example of working conditions here the following table is presented, illustrating the result of the operation of the B. C. Copper Co. for the fiscal year ended November 30, 1907:

J. A. Carahahan, of Canton, Ohio, is back of the $12,000,-
000 company organised to take over a number of prospects at Arcihuervo in the extreme western part of Chiuhuahua.
An average of 17.5c. per lb. was obtained for the copper.

More activity is shown in the development of promising prospects this season than for many years past. This is not confined to any single part of the district, but is seen around Similkameen, Grand Forks, Nelson, and Rossland. As a result several small promising mines are now producing ore. Leasing has been much in favor in Rossland this summer, and two properties at least have benefited from the work done, with the result that when the leases cease the companies owning the mines will carry on extensive work themselves. The earnest work of the prospector and small mine-owner is of great economic value to the mining industry, and these men should be given every possible aid, consistent with good practice, such, for instance, as they have been given in the Slocan in the lead-bonus, and in Rossland, Greenwood, and Phoenix in the geological-survey made of those areas.

The Ymir Mining Co. will spend $30,000 in improvement and development of their property. The main orebody having been recovered in the fractured area beyond the fault, still showing good assay-values, the future for the premier mine of Ymir camp looks promising indeed.

CHICAGO.

The first six months of the year have been full of discouragement for the coal men. The market has been weak, producers have run poor, and there has been little demand for coal. And for the first time in a long series of negotiations before a new labor-contract was made.

The contract, as finally entered into, is substantially the old one in all matters of price and conditions affecting costs. The operators failed to get a closed-shop contract, and the miners failed to get the cost of shot-firing transferred to the operators. Despite these facts, the long negotiations were not without results. For one thing, the miners and operators are now on better terms than they have ever been in the past.

The series of negotiations involved in framing a contract for the entire State, and this strengthens the hands of the conservatives. This is shown in that recently a member of the union at Springfield, Ill., made charges against President Walker, an investigation was promptly held, and, the charges being unfounded, the man was exonerated. This is encouraging news.

The miners in Indiana are now on the same footing as those in Illinois. In Indiana, as in Illinois, a labor contract was arrived at over the objections of a number of coal companies.

One of the incidental changes in the State-contract provides for a powder commission, which is to investigate and settle all disputes relating to powder used in the mines, and which also has large powers relating to the investigation of shot-firing devices, the making and grading of powder, and other technical problems. The commission recently organized, with John D. Wilson, Fred Hauck, and Thomas Holmes representing the operators, and George Woodson, Charles Burch, and P. Christiansen the miners. It is understood that they are to have the assistance of the State and the U.S. Board of Labor, and have their own expert witnesses.

All this will doubtless sound strange to mining men operating in regions where the Western Federation is active, and it is somewhat of a departure for a labor union to be spending money on technical research.

The Mitchell Bill, or Miners' Qualification Act, which was passed at the adjourned session of the General Assembly, went into effect the first of the month, providing that only certified miners of two years' experience are to be employed. The Attorney-General has decided that the term 'miners' as used in the law applies only to the contract-men responsible for a room in a mine. Heavy fines on both operator and men are provided for any violation, and at first it seemed that all mines would have to close while examinations were being held to certify a working force.

However, on assurances from the Governor that if need be he would use the pardoning power to protect men and companies until the commission boards could be organized and certificates issued, this disturbance of business was avoided.

The oil-production continues to increase. In the first six months of the year the completed wells numbered 1498, of which 1262 gave 34,375 bbl. of new production. In June the pipe lines took 38,550 bbl. per day, and for the first half of the month handled all the oil offered for the first time since the field opened. The service was crippled by a fire and the last month oil was pumped to the point of 100 bbl. of the field.

The pipe-line runs for the first six months of the year amounted to 17,541,759 bbl., with very considerable outside tank car shipments, and 20,352,880 bbl. were stored by the Ohio Oil Co. The pools near Birds, in Crawford county, continue to develop, toward the southeast a considerable number of good wells being brought in every month. In general, however, there has been no pressure for rapid development this year, owing to inability to market the full output. Vice-president Donnell of the Ohio Oil Co. has recently issued a circular letter requesting producers to curtail drilling as much as possible. Approximately half the output of the field is now in storage, and there being no signs of Improvement as regards market-deliveries, the company will be obliged to even further reduce its take-ins. Such a development, it is said, will not be fast enough to keep up with the output, but there is naturally a limit to this, and unless production is cut there may need to be a period of reduced prices. It is hoped this may be avoided. Up to the present time prices have been steady at 66 to 68c., and the best of feeling has been maintained between the producers and the big buyer. In the southern part of the State determined efforts are being made to develop a field adjacent to St. Louis. Land is now leased from Sparta to Medora and along a strip nearly a hundred miles long 'wild-cidding' is being vigorously indulged in.

A considerable number of small gas and oil wells have been brought in, but so far nothing of commercial importance has developed. Everyone seems hopeful of the final outcome.

The brick and cement plants are feeling the business depression, as was to have been expected. The Rosiclare lead and fluorspar mine is shut down because of lack of market for spar. This is said to be the result of a too ambitious program of expansion last year. The Fairview Co., has not yet got on its feet financially, though their deposits of spar hold out well. The Pierce holdings north of Golconda continue in considerable demand for 'gravel-spar' which goes to the Illinois Steel Co. The smaller mines are making the usual irregular shipments. While, on the one hand, producers are uncertain as to market, on the other, the steel companies seem equally uncertain as to reserves available for the new open-hearth furnaces. It is a curious situation which should be benefited by closer study and better business organization, since no one who has seen the stopes in the Rosiclare mines can doubt the presence of adequate supplies of spar. In the Wisconsin zinc district and in northwestern Illinois, the mines are resuming, but new work is not being undertaken as it was a year ago. The mill at Platteville, which is 'dry-concentrating' with the use of static electricity, seems to have settled down to a good running gait, and there are, as a result, a number of new developments and sales. The latter are more probable since the fate of Consolidated Zinc does not encourage ambitious mergers.

The Missouri-Copper Mountain copper deposits at Sullivan, Mo., have recently been examined by Chicago people with a view to their development on a much larger scale and the building of a bigger furnace. As the property itself is rich, has only produced a few hundred tons of blister copper, presumably, from the richest ores available and marketed at the time of high prices, it would not seem to afford a basis for expansion at this time. As is fairly well known, however, it and one or two other deposits in the Ozark country are really rich enough, and apparently large enough to support small furnaces during periods of high prices.
MINING AND SCIENTIFIC PRESS
July 25, 1908.

A firm of Chicago brokers is making an effort to reorganize the North Butte Extension Mining Co., the directors of the company having decided to offer for immediate sale $50,000 in notes of the company in denominations of $500, $1000, and $5000, payable on or before six, nine, or twelve months from date, the proceeds to be used in liquidating the company's indebtedness, which aggregated $60,000 on July 1. Of that amount $37,000 is due on the Overman claim, $15,000 in bills receivable, and $8000 on attachments. It is reported that enough of the notes have already been taken to provide for immediate requirements. A. M. Andrews, of Chicago, has been elected a director and treasurer of the North Butte Extension Co., and several attorneys representing the company have been in Butte for some time looking after legal details pertaining to the payment of claims as they arise. It is also said that the directors of the company are planning to provide for a bond issue of $250,000 or $300,000, for the purpose of taking up the notes and to furnish funds for the development of the property.

The stockholders will be called to attend a meeting in New York to consider the proposition. The North Butte Extension is considered to have a fine mining property. Its shaft, which is down 600 ft., is one of the best in the district. Among four or five good veins, the property carries the extension of the Black Rock vein on which the Butte & Superior is sinking a shaft. The extension shaft is being sunk on the Black Crow claim, one of three claims owned by the company outright. On the 300-ft. level a cross-cut was run intersecting the vein, showing it to have a width of 60 ft., but while the character of the vein-filling was good at that depth, the copper content was light.

John Gillie, general manager of the Amalgamated mine and who also is president of the Barnes-King Development Co., ventures the opinion that the latter property is looking reasonably well. It was Mr. Gillie who, after being elected president of the Barnes-King, made an examination of the property and found less than $50,000 worth of ore in the mines to support the capitalization of several million dollars. His report of the condition of the property knocked the price of the stock from about $3 per share to 50c.

The new management has been trying to get something out of the property for the stockholders, and gradually a fair showing is being developed. For several months the returns have been in excess of the expenses, and in June there was a net profit of about $8000.

Butte, Montana.

Washoe Smelter Production.—Davis-Daily Co. Re-organization.—

John D. Ryan on the Copper Situation.—Great Falls Expansion.

North Butte Extension.—Barnes-King Output.

The Washoe smelter is breaking all records in copper production, treating all the ore usually received in normal conditions in addition to about 40% of the output of the Boston & Montana mines. Production is at the rate of nearly 20,000,000 lb. per month. To this total the North Butte Mining Co. contributes something more than 4,000,000 lb., and Butte Coalition in excess of 2,500,000 lb. on its present limited output. The remainder, about 13,500,000 lb., is credited to the Anaconda, Boston & Montana, Butte & Boston, Washoe, Trenton, and Parrott companies, and to a little custom ore. The Original (Clark) Co. is producing about 3,000,000 lb. of copper per month now, and the only other copper-producer in the district at present is the Pittsburg & Montana Co., which is turning out at the rate of about 550,000 lb. per month. The Original is mining an average of 1200 tons of ore per day at present, which yields probably an average of 4% copper. A year ago ore assaying 5% and upward was shipped as first-class, but 5% ore is now given that classification.

What stockholders in the Davis-Daily Co. have long looked for comes in an intimation from Boston that the re-organization of the company may result in another 'holding' company. Several other plans for a readjustment of the Davis-Daily finances have been considered, but so far as known none has yet been adopted. It is understood that an extension of the payment of the money due the Daly estate for some of the claims owned by the Davis-Daily Co. was secured by the payment of $50,000 in cash. The remainder, said to be $75,000, was made payable under the extension on September 1.

John D. Ryan, managing director of the Amalgamated Copper Co., is authority for the statement that the company has no copper on hand. "The price of metal is low, but there is a buying-demand sufficient to take care of the output," he said. "The metal market is in a healthy if not a prosperous condition. We have no copper on hand at present. We have been selling at a lower price than we would like to get, and I can't say when it will be better. Any revival of the manufacturing business will create a good demand for copper, and will advance prices." Speaking of mining conditions as he found them in Montana on his return from the East, Mr. Ryan said: "With the exception of conditions incidental to the losses by flood at the Great Falls smelter, everything pertaining to the copper industry is satisfactory. The smelter will be repaired and started up within four or five weeks. The mines at Butte are doing as well as can be expected. The output of the properties is as large as at any time in the history of the companies, and the cost of production is as low. There have been no disappointments concerning the situation here. Every promise has been made good and more. The people who direct the big concerns operating here are perfectly satisfied." Mr. Ryan confirms the report that he has purchased for himself and others some important industrial enterprises in Great Falls. "I bought for myself and a few friends practically the entire stock issue of the Great Falls Water & Power & Towslee Co. This company owns the dam from which the Boston & Montana Mining Co., the Electric Light Co., the Great Falls street railway, and the flour mills of Great Falls, secure their power, and it also owns the real estate that controls a large amount of water power at the falls farther down the river. A great deal of real estate in lots and lands in and about the city of Great Falls is also owned by the company. We bought the property because we believe in the future of Great Falls, which has so many natural advantages, particularly in the enormous power that can be there developed cheaply." The purchase was made from J. J. Hill, and it is generally believed that H. H. Rogers and other Amalgamated copper men are interested with Mr. Ryan in the purchase.
Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Compressed air for driving vehicles had its origin in a patent issued to Medhurst, in England, August 2, 1800, in which he used compressed air from a reservoir.

The amount of water in a given oil is most accurately determined by means of distillation. The water distilling over with the oil is measured and the percentage calculated from the known volume of oil taken for distillation.

The standard weight of a cubic decimetre of water was fixed by an official body of delegates to a conference held in Paris in October 1907, representing the principal governments of the world. This was determined to be 0.999972 kilogram at 4° Centigrade.

The area of a segment of a circle is approximately equal to two-thirds of the product of the chord and the mid-ordinate. If the ratio of the two be 8 to 1, the area will be correct within about one per cent, and of course correspondingly more correct for greater ratios. The above rule is mathematically correct for the parabola.

Ground limestone is a better material than burnt lime for soils requiring neutralization. Thus it contributes to the life of nitrifying bacteria which liberate nitrogen and potash in forms available to the plant. For this purpose a high degree of purity is not essential, although, as it is the calcium carbonate which performs the office of neutralizing the acidity in the soil, the less silica and alumina present in the stone the better it is. Culms from limestone quarries could be advantageously used in this way if there were sufficient local demand to keep a crusher economically employed. Lands requiring treatment with ground limestone will need from 1½ to 2 tons per acre.

The hydraulic method would undoubtedly be applicable for moving a hill of shale, provided the material be loosened ahead of the stream from the giant, by blasting with deep shots. The plant necessary to accomplish this work is dependent to such an extent upon local conditions, to allow no accurate estimate of cost to be made. Any competent hydraulic or mining engineer would quickly design and estimate such a plant if he had complete, detailed information. A small monitor with a 4-in. nozzle suitable for this purpose sells for $49.00, b. San Francisco and weighs 400 lb. shipping weight. Water, under pressure of at least 65 lb. per square inch, would be required.

Coal ash possesses features of value in coal intended for coking, and hence is not to be considered as injurious. The strength of coke depends largely upon the resistance to crushing afforded by the cell-walls, hence the burden which the coke will carry in the blast-furnace is directly related to the amount and chemical composition of the ash. In this relation the ash must be considered as a fusible mixture; it should possess such a balance between the alkalis, iron, alumina, and silica that it will make a difficult fusible slag corresponding approximately to the formula of a tri-silicate, 2Fe2O3 · 9SiO2. The quantity is also important, the best coke being made from coals produced from the Pittsburg seam in the Connelsville basin, Pennsylvania, which contains 7% ash of ideal composition for the purpose stated. In coal considered as fuel only, the ash represents waste-material. Its economic importance as a retarder (hence a regulator) of combustion is not negligible, but ash is invariably present in quantities far in excess of the benefit it contributes in this way. If the quantity of ash in a coal intended for use as fuel directly, exceeds 7%, the quantity of fixed carbon present should rise rapidly above 62% to compensate, and if the quantity exceeds 15%, the ash should be so low in iron and the alkalis as to produce a pulverulent residue, that is, one which will not fuse and make ‘clinker’ at ordinary fire-box temperatures, which seldom exceed 1800° C. at any point.

The plenum, or compressed-air process of building foundations under water, or in semi-plastic soil, utilizes a box open at the bottom, on the top of which the foundation proper is built. Compressed air is supplied to the box (called a working chamber) at sufficient pressure to keep the water out, and hence men can, by passing through an air-lock, enter the working chamber to remove the material to be excavated, or to guide the foundation as it sinks. The structure is built in the open air, as rapidly as its own weight causes it to sink. When finally completed the working chamber and the shaft are filled with concrete. In the earlier examples of this method, the working chamber and concrete were constructed of timber or steel. In order to eliminate the element of weakness, due to these perishable materials remaining in the finished structure, often causing a plane of separation between the two component parts of the pier, later designers have used a structure built entirely of concrete. The working chamber, shaft, and air-locks are molded around removable steel forms, and hence the entire structure is one homogeneous mass, leaving no free space around or in the pier. Another pneumatic method of building foundations under water is called the vacuum process. It consists in exhausting the air from a cylinder and using the pressure of the atmosphere upon the top of the cylinder to force it down. The vacuum should be obtained suddenly so as to have the effect of a blow. The compressed-air process is the more common method and for most cases has many decided advantages over the vacuum process. The latter is applicable only in silt or sand, but the compressed-air process can be applied in all kinds of soil, and the direction of sinking can be accurately controlled.
**Discussion.**

Readers of the Mining and Scientific Press are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

---

**Cornish Pumps.**

The Editor:

Sir—In your issue of January 18 occurs a description by E. P. Jones of the No. 2 Cornish pump recently erected at the Berry United mine, Victoria, Australia. I beg to submit some notes on the actual running of the pump, which may be of interest:

**NO. 2 PUMP.**

**PUMP RUNNING 61/2 SIX-FOOT STROKES PER MINUTE.**

---

**Conical Bottom Tanks.**

The Editor:

Sir—With a view to eliciting more information for myself and fellow-workers in the cyanide industry, I take the liberty of giving my answer to a query we have all heard. The question is: Admitting that conical-bottom possess advantages over flat-bottom tanks for slime treatment, but that they are not more commonly used on account of difficulties of construction and supporting, why not build flat-bottom tanks and allow the slime to bank up around the sides and form its own cone?

My experience has been that where this is done, instead of forming a true cone the slime forms as shown in the accompanying sketch, and thus cuts down the capacity of the tank unduly. With a cone built of wood or steel this does not occur unless the angle of the apex is too great. At first glance this seems strange, since we might expect that when allowed to form its own cone the slime would rest at its natural slope, and make an ideal cone, having the maximum diameter and minimum height possible under the conditions. I suspect that this is what does happen, but that the natural slope of slime under water is a dead level. It seems probable that the real explanation of the difficulty with the ‘slime cone’ is found in the structure of the slime particles, for when examined under the microscope slime is found to consist of flakes and not of grains, like sand. This being the case they will naturally settle on their flat sides, and settled slime (magnified) may be compared to a heap of shingles.

This is my idea of the trouble with the slime-cone and seems to explain why slime will bank up on itself but slide on some other surface. It is clear that if a tank were high enough the slime might pile up in almost perpendicular walls but still admit of a satisfactory discharge of the settled mass. The question is, how high would it have to be? That is, allowing the slime to form its own cone as stated, how high up would the practically vertical walls extend, and how much bigger would such a tank have to be than a conical-bottom tank of the same settling-capacity and any given dimensions?

The term ‘settling-capacity’ is a hard one to standardize so I will advance tentatively the following definition which will serve well enough for purposes of comparison: the number of cubic feet of pulp per hour flowing into a tank at a dilution of 3 of solution to 1 of dry slime, the overflow of the tank to be clear solution and the underflow pulp thickened to 1 of solution to 1 of dry slime. If anyone has a better definition let him give it, and at the same time tell us what he knows about slime settling-cones.

**Natural Bottom Formed in Tank by Settled Slime.**

---

**Separation of Slime.**

The Editor:

Sir—An article appearing in your issue of April 25, entitled ‘The Separation of Slime in Cyanide Treatment,’ by Horace G. Nichols, has brought to my notice a subject that has apparently received little attention, but one which should be thoroughly understood by those engaged in the operation of slime-plants. Mr. Nichols seems to understand his subject, and he has presented it in a very interesting manner; but as his subject is not as new to some cyanide metallurgists as he apparently believes, and as I have understood it for several years, I desire to discuss and emphasize some of the points mentioned by him.

It may be of interest here to note that two of my
friends covered a similar field of investigation in South Africa about ten years ago. They have since devised a process, which is broadly covered by patents, embodying all the principles mentioned by Mr. Nichols, as well as others that carry the subject still farther. That a mixture of dry slime and water has a definite specific gravity, which varies with the percentage of solids, is commonly known and applied in the operation of cyanide works, but that the mixture behaves like a dense liquid is often overlooked. Slime-pulp, which is not in a state of agitation, tends to settle and the percentage of moisture decreases toward the bottom of the vessel; also the specific gravity of the mixture increases in the same direction, so that the variation will be from 1 at the top to that of the oaked slime at the bottom. A particle settling in such a medium has, therefore, an increasingly slower rate of settlement, or an increased retardation, as the density of the pulp becomes greater; it follows therefore, as Mr. Nichols has pointed out, that the rate of settlement will be increased if the densest or lowest stratum is continuously removed. The rate of settlement does not, however, depend entirely upon the density of the pulp but upon various factors such as the dilution of the pulp; physical and chemical character of the slime; size and shape of the particles; chemical constituents of the solution: uniformity or non-uniformity in the size and specific gravity of the particles; depth and diameter of vat, and so forth.

Mr. Nichols’ two laboratory experiments demonstrate clearly the influence of dilution and relative depths of pulp upon the rates of settlement, and his process, in common with that of my South African friends, is distinctively a continuous process. The great objection to such a process, as compared with filter-presses, is in the enormously greater amounts of solution to be pumped. Such a process, however, permits of more thorough washing and the cost of maintaining and operating it would be very light indeed. I suggest that the low percentage of moisture, in the first sample (Table 6 of Mr. Nichols’ article), is due to the large amount of granular material probably contained in it. All the fine sand and sulphides would have settled within 15 minutes, and these would make a denser cake than the more flocculent material, which settled later. Such being the case, the average moisture in practice would probably be between 25 and 30%. I know, however, that it is entirely feasible to obtain settled slime containing 22 to 30% moisture, and to remove it as fast as it accumulates.

The arrangement of the particles of slime has an important bearing upon the percentage of contained moisture, and, in the operation of a filter-press the percentage of moisture in the residues will depend within certain limits, upon the way the press is handled, the pressure employed, and the manner of charging. As a case in point, take the cakes formed in a Dehne press, consisting of an average amount of granular material, and containing about 25% moisture; such a cake would be very solid and apparently quite dry. If, however, dry slime be mixed with water in such a proportion as to contain 25% water, the mixture will be fluid and run like thick mudsasses.

As regards over-sliming, cases are not infrequently observed where the pulp is ground finer than is necessary for purposes of extraction, simply to enable the agitation plant to treat the pulp mechanically. Such a misfit plant has no excuse nowadays and it is a relief to know that, from a treatment and mechanical standpoint, it is no longer necessary to worry as to whether the ore is suited to treatment by the cyanide process or not. It is now feasible to treat anything from boulders to slime. Slime can be leached and coarse sand can be agitated, so that between the two all possible variations can be pretty well covered.

Champaign, Illinois, May 7.

H. T. WILLIS.

Cost-Keeping.

The Editor:

Sir—One of the essentials of successful mining consists in the keeping of costs. To accurately follow and control the itemized cost in each department is an essential to an economical production. It is impracticable to personally supervise operations in any undertaking, whether mine, factory, or business, except in small concerns. The time comes in any organization when operations are entirely beyond personal observation and control. It is then that a perfected and detailed system of costs is of essential importance to a mine manager. The ideal manager is he who, while never having to leave his office, yet is perfectly posted by daily, weekly, and monthly reports and cost-sheets. In other words, everything must come to him and be self-explanatory. A daily labor-sheet handed him that same day will tell him far better how many men are employed and how disposed, than by a tour of the surface or underground. It is even possible in some undertakings to strike a rough daily balance of profit or loss.

From labor tickets is compiled the daily labor-cost, segregated into the several accounts of each department. These are then entered on the day-line of the monthly sheet, and thus at the close of the month costs are rapidly and accurately ascertained. All such sheets should be of standard size, colored for the several distinctive classes of labor, and filed in loose-leaf binders. To facilitate the charging of both labor and material it is advisable to adopt a definite number-scheme, so that each item shall be specifically charged, and shall be immediately available to the cost-clerk. It is suggested that the mine have numbers, 100 and upward; the milling department, 200 and upward; the mechanical, 300 and upward; the general expenses, 400 and upward, and construction numbers beginning at 500. The advantage of this scheme is that one sees at a glance to what department the cost is to be charged. For special work in the shops, perhaps the issuing of a job-order ticket, to be returned when completed, with time and charges, is as good as any. The miscellaneous small jobs that pass through the shop are always fruitful of trouble. Most large establishments have such a scheme.
There seems to be too large a latitude in the charging of costs. Many are unintelligible and some appear to be actually false. Such costly items as development, timbering, pumping, and general charges are switched around in the office, and are either buried where desired, or even run into construction-accounts. This is probably due to lack of intelligent information. With a definite number-scheme, there are few items on which the cost-clerk has the option of a private opinion. All numbers are not accurately given, but the errors are not serious and are often detected. Revenue account is kept entirely distinct from construction. In mine-development, for instance, there is always latitude for personal expression. This should be governed by the manager, on lines definitely laid down, and thus be returned to the office. It seems desirable to keep development costs down to the lowest figure, and charge as much as legitimately may be possible direct to stoping. All work in connection with the blocking out or breaking down of ore goes to the stoping account direct.

Development should be a distinct asset to the mine. For instance a main working drift would be chargeable to development, while the intermediate drifts and cross-cuts to the ore would be a charge against stoping. Some firms do not carry a development account, claiming that if the ore does not meet the costs from month to month, or from year to year, the sooner they know that fact the better.

A restricted development account is desirable to spread certain costs over a period of years. To bolster up stoping costs at the expense of development account is inaccurate. To carry an inordinately large development account and then at the end of the year magnanimously write off, in part or whole, against the alleged profits, is also fallacious, unless such writing off is recognized as an operating expense. Under normal conditions development is a working cost and should be treated as rationally and candidly as any other working cost.

Sampling of Mine Dumps.

The Editor:

Sir—The article on 'Sampling of Mine Dumps,' which appeared in your issue of May 23, brings to mind a method which I employed some years ago in the determination of the volume of two old Spanish dumps. These were situated on a steep mountainside, along the crest of which out-cropped the vein. About 20,000 tons had accumulated from an open-cut working, and another pile of about 52,000 tons had been discarded at the mouth of a cross-cut tunnel 400 ft. deeper. Exigencies of time precluded the sinking of shafts for sampling, but it was known that little or no work had been done outside of the orebody by the Spanish and Mexican operators; that the dump surface represented the discarded material from poor stopes; and that it had been sorted over several times during the past 25 years. Thorough surface sampling established the fact that for the particular locality, the discarded quartz was of sufficient value to warrant its being considered fair pay-ore, and, in view of the reasons set forth above, and of the fact that the mine had gone through several 'bonanza' periods, it was considered reasonable to accept the value thus obtained as being a conservative figure for the pile. In the absence of shafts to ascertain the depth and tonnage at different points, the determination of the volume was made as follows: The mountain-side was cut by many small gulches, pretty well defined, and it was considered probable that the evidence obtained from a topographical survey of the surrounding ground would fairly define the ground-surface under the dumps. The survey of the dumps and adjacent hillsides was therefore made with this in view; careful note taken of the limits of the former, and of the gulches and depressions on all sides. These notes were plotted to 5-ft. contours, to an assumed datum; the hill-side contours drawn in solid black and the dump-surface contours in red ink. The gulches and depressions now shown plainly by the black contours, were examined with a view to determining their probable continuation under the dump, and these positions were then sketched in, to serve as a guide for the change in direction which would result in the contours at these points. Those assumed under dump-contours were now dotted in with black ink, and made as consistent as the evidence would warrant.

We now have a plan, the dotted black and red contours of which, for the same elevation, circumscribe horizontal sections of the dump at 5 ft. vertical intervals, and if the assumed contours are correct, we could, by the aid of a planimeter and the prismoidal formula, accurately determine the volume and tonnage. In the absence of a planimeter a 10-ft. cross-section sheet was prepared on tracing-cloth to the same scale as the drawing, and tacked over the latter.

It is evident that the vertical depth of the dump at any point, may be found by noting the dump-surface and 'under-dump' ground-surface elevations at that point; thus, at the intersection of a red and dotted-black contour, the depth would be the difference between the elevations represented by the respective intersecting contours. By this means estimate for the depth of each 10-ft. square was made and noted, and the aggregate volume and tonnage determined. Some time later, shafts were sunk many samples were taken and the assay returns gave a result more than 50% higher than the value indicated by surface-sampling. The value of the different strata accurately told the story of the mine's bonanza days. The most interesting feature of the sinking, resulted from the very close check on the assumed 'under-dump' contours. In some cases the depth proved greater, and in others less, but these differences so nearly compensated, that the original tonnage estimate was allowed to stand.

Glacier ice is now used by some of the larger consumers of Lyons, France.
THE GENESIS OF BENDIGO AND CARRICK LODES, OTAGO, NEW ZEALAND.

Written for the Mining and Scientific Press
By James Park

In Bulletin No. 5 of the New Zealand Geological Survey, lately issued, I have given a detailed description of an interesting group of gold-bearing lodes at the Bendigo and Carrick goldfields. The lodes are enclosed in a moderately hard mica-schist of Paleozoic age. The schist is singularly free from folding, but is traversed by a series of powerful faults between which wide strips have subsided, forming valleys and lake-basins, or what German geologists would call graben. The strips that were left standing now form one of the most interesting groups of 'block mountains' to be found in any part of the globe. These table-topped mountains were first brought to the notice of geologists by myself in Bulletins No. 3, issued last year. A noticeable feature of this region is the absence of dikes and igneous intrusions. The country is high, arid, and bare, the meagre rainfall of 12 to 15 in. per year being insufficient to support more than a scanty vegetation. It is in this region on the margin of the Cromwell basin that the Bendigo and Carrick goldfields are situated.

A close investigation of these lodes shows that they are 'lode-formations' rather than true lodes. By this I mean that they are mineralized zones of crushed rock. Their main characteristics are so persistent and distinctive that they form a type of lode for which the name immature replacement lodes seems a not inappropriate designation.

As I have pointed out in Bulletin No. 5, previously mentioned, and here largely reproduced, the chief characteristics of this type of deposit are:
1. They lie between two parallel fractures, on which more or less faulting has taken place.
2. They traverse the country rock independently of the planes of bedding or foliation.
3. The lode-matter lying between the walls consists mainly of crushed rock traversed by veins of quartz.
4. The crushed rock is more or less silicified and replaced by quartz. The extent of replacement is variable, even in the same lode.

Commonly the quartz was deposited first along the walls, giving sometimes, as in the case of the Caledonia lode on Carrick Range, two opposite, parallel, and contemporaneous veins separated by a zone of crushed rock. In other cases the quartz was deposited on one wall only. In some places the crushed rock is replaced by vein-quartz from wall to wall, but in all the lodes the bulk of the lode-filling is crushed rock. Where the first condition prevails we have what might be termed a true quartz vein, and where the latter condition prevails, a 'mullocky lode.' Between these two extremes we can trace every stage in the evolution of the massive quartz-vein; and in this we have a valuable and instructive object-lesson in the genesis of ore deposits that occur as veins.

The veins traversing the crushed rock consist of crystalline quartz, sometimes containing a small proportion of scheelite and pyrite. They generally lie nearly parallel to the walls, and are subject to great variation in size and direction, even in a short distance. In the blue oxidized ground the rock and quartz are often brecciated and strongly slickensided. It is obvious that wall-movements took place.

Fig. 4. Longitudinal Section of Lode, Showing Depth of Pay-Ore.
during the formation of the quartz veins. At Bendigo the lodes traverse almost horizontal micro-schist, and at Carriek Range they traverse strata which are generally steeply inclined. At both places there is entire absence of igneous rocks. The fault-fractures in which the lodes lie are local, that is, they have no tectonic or structural significance, and in the absence of igneous rocks showing at the surface we can only conclude that the fissuring was caused by the intrusion of an abyssal magma that solidified so far from the surface as still to remain uncovered by denudation. The presence at Bendigo of scheelite, and the somewhat rare tarnstungite of lime, at Carriek Range of antimony, and at Waipori of cinabar in similar lodes, would tend to support the contention that the metalliferous emanations and solutions ascended from below by cracks and fissures connected with the intrusive magma. The formation of a simple fissure, or even of a system of more or less parallel but distinct fissures, in rocks subjected to tension or shear is easily understood; but in the case of these lodes we are dealing with twin fissures, enclosing between them a narrow slice of country rock commonly crushed and more or less replaced by quartz. The mechanics of the stress or stresses that led to this twin fissuring is at present difficult to explain satisfactorily. The unusual character of the Otago lodes at Skippers, Macetown, and Waipori was noticed by T. A. Rickard* as far back as 1893. He thinks they belong to a type of ore deposits more common than is supposed.

Concerning the age of the lodes only the most meagre information is deducible. It is certain, however, that the lodes existed and were subject to denudation during the Pliocene period, since gold-bearing quartz derived from them is found in the Pliocene quartz drifts. They exist in rocks of probably later Paleozoic age, and are undoubtedly older than the Pliocene. But there are no data that would permit of ascribing them to any definite period.

The arrangement of the old workings leaves little doubt that the best returns were obtained in the upper part of the oxidized zone, at a depth generally less than 50 ft. below the outcrop. It has already been stated that rich pay-ore followed the contour of the ground, but did not descend vertically to a great depth. The ore was not equally rich everywhere along the outcrop, but no information is now available as to the length or pitch of the various pay-shoots.

Take the following case: Let Fig. 4 represent the longitudinal section of a gold-bearing lode. Let the shaded portion represent the depth of pay-ore, and let the top of the hill at a be 200 ft. above the hollow at b. To say in this case that the lode contained pay-ore for a depth of 200 ft. because a is 200 ft. above b would be incorrect, for the depth of pay-ore is, relatively to the surface, the same at a as at b. If pay-ore were proved by a shaft, drift, or cross-cut to exist 200 ft. vertically below a, only then would it be correct to say that pay-ore existed down to that depth. In the example, a drive at b on the line of the lode would soon run out of the pay-ore.

It is also obvious that a cross-cut from the hillside at any point 40 or 50 ft. below the outcrop would pass below the rich ore into poor ground. With lodes of this class, long low-level drifts and cross-cuts seldom or never meet with success. The best practice is to keep on, or as close to the gold ore as the local circumstances will permit. The manner in which the pay-ore follows the outcrop clearly establishes a definite relationship between the surface-form of the ground and the zone of enrichment.

The blue unoxidized ore from the deep ground at Carriek Range was commonly lean, being seldom rich enough to pay for working out. In the brown oxidized ground the ore was generally highly profitable, and, as we have just seen, descended to a limited depth below the outcrop, whether on the hilltop or steep slope. Hence we have reason to believe that the rich ore in the oxidized zone is the result of what is termed 'secondary enrichment.' In accordance with this principle it is assumed that as the outcrop of the lode during countless ages became worn down by denudation the gold was liberated. A portion of this gold was carried into the neighboring wash-dirt, while another portion was dissolved by mineral acids, liberated from the decomposition of the contained iron-sulphides, and carried downward in solution through the upper oxidized zone, where it was re-deposited in the crushed rock and clay, thereby enriching the existing lean ore, which thus became payable. The precipitation of the gold in this process of concentration presents fewer difficulties since Skey, Kohler, and Weed have shown that clay and finely divided mineral matter possess the power of absorbing or extracting metals from their dilute aqueous solutions. In secondary enrichment we also have a satisfactory explanation of the circumstance that the rich pay-ore follows the contour of the ground along the outcrop of the lodes.

A volumetric determination for lead given by Boltenbach is as follows: To the Pb solution is added NaOH in amount sufficient to re-dissolve the precipitate which at first forms. The mixture is then diluted to a known volume, and 50 c.e. of this is run slowly into an excess of standard $\text{KMnO}_4$ of known volume, which has been mixed with 400 c.c. of hot water, and 5 c.c. of an 8% NaOH solution. Agitation while mixing the solutions is necessary. The excess of $\text{KMnO}_4$ is then determined by the use of $\text{N}_2/10\text{Pb(NO}_3)_2$ solution, the end reaction being the disappearance of the pink color, in the supernatant liquid. The reaction occurring is:

$$6\text{Pb(NO}_3)_2 + 2\text{KMnO}_4 + 12\text{NaOH} =$$

$$2\text{MnO}_4^- + 3\text{Pb}_2\text{O}_4 + 2\text{KOH} + 12\text{NaNO}_3 + 5\text{H}_2\text{O}.$$  

**Coal production of the United States for 1907 as given by the U. S. Geological Survey amounted to 480,450,042 short tons having a value of $814,831,549. As would be expected Pennsylvania produced more than any other state, being credited with 236,000,000 tons, of which almost exactly two-thirds was bituminous coal. Illinois, Ohio, and West Virginia rank next to Pennsylvania in the order named. Idaho, Nebraska, and Nevada combined produced only 7588 tons.**

REINFORCED CONCRETE TANKS.

Written for the Mining and Scientific Press
By L. Mess.

The improvements obtained in the last few years by using reinforced concrete for the most difficult kinds of construction is to be considered at least as important as the progress obtained in mechanical and electrical engineering. One of the latest adaptations of reinforced concrete is to the construction of tanks for water, oil, gas, cyanide solutions, slime, and for all common as well as corrosive liquids. Europe has been several years ahead of the United States in this work. The first attempt in this direction was by Joseph Monier at Paris, said to have been the production of cement flower pots and vessels large enough for shrubs and trees. As early as 1868 he had employed the new material in constructing water tanks of large capacity. The success of these was so great that in a few years Monier's reinforced concrete was extensively adopted in Germany and Austria for tanks and reservoirs.

In the United States one of the largest concrete water tanks is in the town of Attleboro, Mass. Attleboro was supplied with water up to the spring of 1904 from a wrought-iron stand-pipe 30 ft. diam. by 125 ft. high, holding 600,000 gal. of water. In March 1904 a break in the line, immediately after a fire, showed the authorities the necessity of building
another and much larger water-storage reservoir to hold 1,500,000 gal. The water of Attleboro, though of excellent quality for domestic and manufacturing purposes, contains carbon dioxide in such quantities as to attack wrought-iron and steel and to greatly shorten the life of an iron stand-pipe, nearly two tons of rust being taken out of the old stand-pipe annually. On making estimates for the new reservoir it was found that one made of reinforced concrete would cost about $3000 less than if built of steel. The structure as built is 50 ft. diam., 106 ft. high, with walls 18 in. thick at the bottom and 8 in. thick at the top, the batter being all on the outside of the wall. The inlet pipe rises to 40 ft. above the bottom and the water is compelled to leave the tank through a 24-in. pipe in the bottom, thus insuring circulation. Above the top, cornice openings are made all the way round the tank, affording a uniform exit for the water in ease of overflow, so that no washing of the concrete can occur at any one place. On one side rises a wrought-iron ladder, held in place by bronze bolts.

A remarkable elevated tank of reinforced concrete was recently built for the Anaheim Water Co., at Anaheim, Cal. It is the first tank of its kind ever constructed in the United States. It is 32 ft. diam. by 38 ft. high, supported on concrete posts 70 ft. high above the ground. It has a capacity of 200,000 gal., and is made throughout of concrete, reinforced with rings and vertical members of twisted steel. The walls of the tank are 3 in. thick at the top and 5 in. at the bottom. When tried and tested it was found to be as tight as a bottle, without appreciable cracks. The floor is supported by concrete beams radiating from the centre, and the twelve posts, each 16 in. square, are stiffened by two lines of horizontal struts at equal intervals above the base. The foundation of the tower consists of a heavy slab of reinforced concrete extending 4 ft. into the ground. The tank has a conical-shaped roof, also of concrete, 2 in. thick, with a cornice over the edge, slightly raised to afford ventilation for the water within. From the lowest foundation to the extreme top the tower has a height of 112 ft. It is graceful in outline, and yet gives a pleasing appearance of massiveness and solidity. The cost was about 75% of the lowest estimate on a steel tank and tower of equal dimensions.

The water tower recently built at Fort Revere, Boston Harbor, is one of the most interesting examples of deep-tank construction in the United States. From the ground surface to the apex the height is about 93 ft. The tank inside the tower has a diameter of 20 ft., leaving an annular space between the tank and the inside wall, which is occupied by a spiral stairway leading to the observatory.

Reinforced concrete tanks have repeatedly been proposed for use as cyanide tanks, slime tanks, solution tanks, as well as leaching and percolation tanks. Though the cost of reinforced concrete tanks depends on the shape and size, yet the cost is not in the same degree dependent on the size as is the case with steel or wooden tanks, that is to say, larger reinforced concrete tanks are proportionally cheaper than steel tanks. The durability of steel tanks is limited to about 20 years at most. In countries with a changeable climate the limit is from 7 to 8 years. In countries with hot climates steel tanks may warp after 2 or 3 years. Therefore, in spite of all their disadvantages, wooden tanks are generally chosen because of their freedom from the drawback of rusting which destroys steel tanks. When cement can be had at reasonable rates there is no doubt that it should be employed in preference to either steel or wood in the construction of mill-tanks. With ordinary reinforcing they will resist vibration indefinitely.

---

### The Prospector

This department makes a charge of 25 cents to subscribers not in arrears and $3 to non-subscribers for each determination.

W. M. Manhattan, Nevada: No. 1, pyrite in quartzite; No. 2, traces of graphite in crystalline limestone; there were seven unnumbered pieces.

S. G. M., Hermosillo, Mexico: No. 1, quartzite with iron stain; No. 2, pyrolusite, hydrous oxide of manganese, pseudomorphous after manganite.

J. W. O., Piute, Cal.: No. 1, quartz with tale, somewhat crushed; contains pyrite and a trace of chalcopyrite; No. 2, greatly altered basic biotite-granite.

A. B. R., Hart, Nevada: No. 1, crystallized magnesian or dolomitic limestone; No. 2, silicified rhyolite with some sulphides in white seams; No. 3, biotite-granite.

W. G. S., Custer, Idaho: No. 1, augite-andesite, with feldspar crystals partly kaolinized; No. 2, altered andesite, showing small seams filled with limonite. Action of mineral waters.

O. B. A., Chloride, Arizona: No. 1, schist; an altered, very fine-grained sediment; crystals, probably sillimanite, throughout; has been acted upon by carbonate waters and filled with carbonates of lime and iron; No. 2, hornblende-andesite; the hornblende is now converted wholly into limonite.

F. J. G., Grass Valley, California: The Mining and Scientific Press does not analyze rocks. The specimen sent is too highly decomposed for precise identification. It now consists of limonite and chlorite. The chlorite was probably derived from hornblende, and the rock seems to have been originally a basic igneous plutonic, a hornblende.

A. J. Boyer, Nevada: No. 1, andesite, greatly altered and containing chalcopyrite changing into chalcocite; No. 2, schist fragment with chalcopyrite, chalcocite, and malachite; No. 3, sintered mass left after decomposition of sulphides; contains limonite, cuprite, and malachite in decomposed rock; No. 4, bornite with malachite and limonite; good copper ore; No. 5, andesite, decomposed and partly filled with malachite.
TAILING DISPOSAL AT MERCUR, UTAH.

Written for the Mining and Scientific Press
By H. W. MacFarren.

The product of the Golden Gate mill of the Consolidated Mercur Mining Co., after being crushed dry is treated in 27 rectangular iron vats, 25 by 50 by 5 ft., each vat holding 240 tons and having 8 bottom-discharge doors. These vats form one solid row 700 ft. long with four car-tracks lengthwise underneath for disposal of tailing. This tailing is transferred, by contract, from vat to dump at a cost of about 8 cents per ton.

Seven laborers in gum boots, as the ore is exceptionally slimy and consequently wet, drag and pull, rather than shovel, the tailing into cars underneath, where one man is constantly employed 'spotting' the cars. Cars are of the side-wing dumping type known in mining camp parlance as the 'battleship' car, holding four tons each. Two trammers complete the crew of 10 men. Two 8-hour crews dispose of the daily capacity of four vats.

The filled car is pulled by a horse on a trot to the dump, where a movable platform is used to facilitate dumping operations. Arriving near the platform, the trammer (from his riding step at the front of the car) unhooks the single-tree and quickly turns the horse to the side of the track. The momentum of the car carries it onto the dumping-frame, and since the frame is set with an up-grade, the car starts back when the residue is out, the trammer gets hold of his horse, and is off again for the vat-room on a trot. The celerity and precision with which the whole operation is performed makes it an interesting one to watch.

The photograph and drawing will explain the dumping-frame and its use. In the illustration it will be seen that the sand has been dug away from the frame; plank and rollers have been placed underneath; it will now be 'barred out' as far as safe, the plank and rollers removed, the track connected, and the cables anchored to a log cross-wise underneath the track and 60 ft. back: then this track is ready for use. As the top of the dump is over 200 ft. above the ground, a large amount of dumping space is available. The frame is built of as heavy timber as is necessary to sustain five tons safely, but two experienced men find no difficulty in moving it forward into a new position. In the background the two trammers are indistinctly seen at their work. This frame has been used at all the other mills in the Mercur district with entire satisfaction.

A remarkable airship flight is reported from Switzerland. A dirigible balloon maneuvered over Lake Constance for 6½ hours on June 29. The gas envelope is 445 ft. long, and has a diameter of 49½ ft. The ship carries three motors of 145 hp. each, which actually developed an average speed of 34½ miles per hour and a maximum of 38½. It carried 14 passengers, and without casting ballast attained a height of 1000 ft. Communication with the earth was maintained throughout the trip by wireless telegraph.

Verniers, of an engineer's transit, may be more accurately set at the zero mark if care be taken to have the lines on the scale coincide with those of the vernier, not only at the zero of the scale but also at both ends of the vernier.
GOLD MINING IN PORTO RICO.

Written for the MINING AND SCIENTIFIC PRESS
By WILLIAM B. MCKINLAY.

(Continued From Page 98.)

The first town on the island of San Juan was established by Ponce de León in 1509, and was called Caparrra to signify the fact that the settlement of the island, as desired by the King, was definitely inaugurated, the word meaning a token or earnest. Caparrra was situated on the north coast, so as to be near the mines which the Spaniards had commenced to work, but in an unhealthy marshy lowland across the bay from the present capital, which was established in 1520. The first gold of any consequence taken from Porto Rico was obtained by Ponce de León. He had it melted in España, and it was made into a large chain. The records show that the chain was valued at 8975 pesos and 3 tomines, so that the royal tax would have been 1795 pesos and 7 granos. It arrived in Spain in August, 1509.

The following system of weights was used for weighing gold at the time of the conquest, and it still survives to some extent in parts of Spanish America:

The first melting of gold on the island of San Juan or Puerto Rico was done by order of Ponce de León on October 26, 1510, at Caparrra; and the royalty of one-fifth amounted to 2645 pesos and 4 granos. The next was on May 22, 1511, on which the royal fifth amounted to 3043 pesos, 5 tomines and 6 granos. There was evidently another melting very soon after, for on August 7 Ponce sent 10,000 pesos to the King as the royal share of the gold mined up to that time.

On September 9, 1511, the King wrote to the officials in Seville, saying: "I am delighted to learn that 10,000 pesos of gold came from San Juan. I did not expect so large a yield as soon as this. It must be, as they say, that the mines are better than in España." On the same day he wrote to the Admiral, telling him to favor Ponce as much as possible. Although the King wanted to have a model colony, it was not an easy matter to induce people to settle there. By royal decree one need only apply to the officials in Seville, and need not give further information, indicating that a criminal record in Spain would be no bar to a prospective colonist. In 1512 the gold output was not very large. A shipment of 6000 pesos was made early in January, 1513, and a shipment of 284 pesos and 4 tomines of unmelted gold was made at the same time, to show the people of Spain how the gold looked when taken out of the mines. This was also a royal fifth, so the total production for 1512 amounted to 31,171 pesos and 4 tomines.

In 1513 the King issued a set of ordinances which contained thirty-five excellent provisions, and many suggestions were made, not only for the good of the Indians, but for the general colonization of the island. As a result, special efforts were made to compel all bachelors to marry, to compel those colonists who were already married to send to Spain for their wives, and to provide for the allotment of Indians to the married men in preference to bachelors. The mining industry took on new life in this year, for on April 21, 1513, the first melting of gold in the new town of San German yielded 30,737 pesos and 3 granos, of which the King received the usual fifth. This was almost as large as the melting at Caparrra, now called the city of San Juan, on August 1, which amounted to 36,875 pesos. They probably had one or more meltings at Caparrra earlier in the year, for the officials at Seville received gold from San Juan on August 2, 1513, three boats bringing 16,057 pesos and 1 tomin as the King's fifth, the San German melting of April very likely being included in the shipment. In the year 1514 the official records show an apparent falling off in the gold production, but a letter written by the King to the Treasurer of the island sheds some light on the subject. Among other commands, he says: "As to the abuse of carrying off gold without having it melted, remedy it." This indicates the smuggling of gold away without paying the royal tax. In 1514 the melting at Caparrra yielded 3482 pesos 4 tomines and 6 granos for the royal fifth, and the records show that in San German there were three meltings. Two meltings of placer gold, made in February and June, gave a total of 7243 pesos and 4 granos for the King's share; and in June a special melting of gold from "nacimientos" yielded 2763 pesos, 6 tomines and 8 granos, of which the King received only a tenth part. This is the first record of gold mined from veins in the island of Porto Rico. The word vein is used for want of a better one. Nacimiento means the source or origin, and it is not reasonable to suppose that the Spaniards would have applied that name to placer deposits. It is probable that, in searching the smaller streams for pocket placer-deposits, some of the miners discovered outcroppings of gold-bearing rock in the beds of the streams. As the decomposed rock would have to be pounded to fragments to liberate the gold contained in it, the officials deemed it proper to exact a tax of only a tenth part, instead of the usual fifth as levied on placer gold.

Such deposits have been worked in Porto Rico in recent years with implements as crude as those employed in the sixteenth century. In 1900 the writer bought, from a vagrant native prospector, gold which showed none of the marks of placer gold. The native gave a very clear description of the nature of the deposit and of the antique methods by which he extracted the gold; but how rich and ex-
tensive that particular deposit is will not be known until he can be induced to sell the secret of its location, or until some other prospector runs across it. It is at the eastern end of the island, somewhere in the hills between the villages of Ceiba and Manuyes. A violent storm, called ourucán or huracán by the natives, did considerable damage in the island in the year 1515; and in the fall of the same year the caciques Humeneo and Daguan started a revolt which lasted some time in the southeastern part of the island. Notwithstanding all these troubles, the gold output was quite large. The officials in Seville received several shipments of gold from the island, the royalties amounting to 23,492 pesos. Of this, 2000 pesos represented the one-tenth share of gold from nacimientos; the balance being the regular fifth from the placer product. In 1516 some of the indignant settlers drew up a set of recommendations and sent them to the King, in the hope that grafting officials might be punished, that favorites might be put out, and the unnecessary offices which had been created for them (such as mining notaries who ex-
royalties for 1517 amounted to at least 13,000 pesos and probably much more. Andrés Haro, the treasurer, wrote to King Charles in January, 1518, saying: ‘‘They have been melting in each of the three meltings in the last two years, 250,000 pesos in this city and in San German 186,000. But this varies.’’ While this would indicate that the amounts as stated in Table 2 are entirely too low, the statement of Haro is not sufficiently definite to make it the basis of an estimate. In 1518, 25,497 pesos reached Spain as the King’s royalty. In this year the priests of the order of San Gerónimo sent to the new king an urgent plea in behalf of the ill-treated Indians; saying: ‘‘They should be set free or at least excused from compulsory mine work, which is killing many. About a third have taken to the hills, where they are unassailable. They have killed many settlers, and it is unsafe to go among them. The best plan is a new allotment, giving the Indians to the respectable married men, and not over eighty to each. Mining should be abandoned in favor of cultivating the soil, and all Indians capable of self-government should be freed.’’ Some of the priests thought that it would be unjust to free the Indians, on account of the loss to the owners, and recommended that if the Indians were freed each settler should be given one black slave in exchange for every five Indians taken away from him. About this time an epidemic of small-pox ravaged the island, and many natives died from this cause. The Spaniards suffered to some extent from this and other diseases, and the mortality among the children was very great, especially in Caparra. The moving of the capital, a question which had been discussed for several years, was definitely decided in July, 1519; and the sentiment of the majority was that the move be made at an early date, and that if Ponce de Leon did not care to move with them he could himself live in Caparra as long as he pleased.

Two shipments of gold were made in the year 1519, being of 10,000 pesos each; the second one reaching Spain in January of the following year. In 1520 there were five small shipments, aggregating only 15,734 pesos, and if the royal fifth did not exceed the amount of these shipments the total production for the year was only 78,670 pesos. Although the royalties from 1516 to 1520 have been taken as being a fifth of the production, it is probable that some of the gold came from the nacimientos and only paid a tax of one-tenth, and the figures of the total production should be somewhat increased; but in estimating these quantities only the lowest figures are taken, so that it will be impossible for exaggeration to creep in.

The decrease in the production was partly due to the moving of the capital. On November 16, 1520, Baltazar Castro wrote to the Emperor (as Charles the Fifth was now called), stating that the city of Puerto Rico had been transferred to an islet across the bay from the old location of Caparra. In 1520 almost a third of the yield came from some newly-discovered mines, probably in the vicinity of Luquillo, near the eastern extremity of the island. On account of the scarcity of Indians, due to their extermination and flight, slaves were obtained at great expense from the firms which had the exclusive right to import negroes. The officials recommended to the Emperor that as an inducement to continue mining under the new labor-conditions, the royal tax should be reduced from one-fifth to one-tenth. In the latter part of 1520 this was done.

As the tax on gold had been reduced to a tenth, the miners were encouraged to renewed activity; and the output reached 98,993 pesos and 6 tomines in 1521, and 189,700 pesos in 1522. From 1523 to 1529 the records are not very clear as to the production. Some historians estimate the royalties to have amounted to 40,000 pesos for the seven years. Keeping well within that limit, an estimate of the production as averaging 50,000 pesos per year is sufficiently conservative. On October 4, 1526, a severe hurricane occurred, and almost every house in the island was destroyed; the high water doing so much damage that many settlers lost practically all their property. About two years later a French war vessel or privateer landed on the west coast of the island and sacked and burned the settlement of San German. The settlers became discouraged, and in 1529 the officials asked the Emperor to provide artillery for defense against pirates. They also asked that concessions, such as the free importation of negroes, be granted to encourage the miners; saying that only one mine was in operation. Although no concessions of importance were granted, except the extension of the one-tenth tax on gold, the miners took out 132,400 pesos in the beginning of the year 1530, the royalties reaching Spain in June and July. Then, in the middle of the summer, disaster came to the island in the shape of three violent hurricanes. These occurred on July 26 and August 22 and 31.

The hurricane of 1599, during which I experienced some thrilling adventures in aiding less fortunate victims, was but a summer storm in comparison with the successive hurricanes of 1530. Not only did the storms destroy their houses and crops, but there was no kindly government close by to rush supplies of beans, rice, spring bonnets, and silk petticoats to the suffering inhabitants. To make matters worse, there were two more hurricanes in September, and the Caribs came after fresh meat again; murdering many settlers and carrying away twenty or thirty Indians and black slaves. The inhabitants of the islands were so terrified that the women and children were afraid to sleep in the rude shelters which had been improvised, and took refuge in the churches and other stone buildings. Notwithstanding the condition of the island, mining was not abandoned, for in 1531 a total of at least 25,000 pesos of gold was taken out. In June, 1532, the officials wrote to the Empress to the effect that: ‘‘Up to this time, ordinarily everybody got gold in the rivers. Finding very little in these, after the hurricanes, the people have searched in the hills and they have found two or three veins from which comes very good gold. But these have been held by three or four who discovered them. The rest, on account of debts and lack of negroes, can not go prospecting, and they are lost. If you would
give general permission to bring slaves without having to buy at a high price, from those who have a government monopoly, they would get plenty of gold.'

The production jumped to 90,000 pesos in 1532, and prospects began to look brighter. Early in 1533 one writer stated that the island was beginning to get populated again, and that every day new mines were being discovered, and also new veins of gold. Notwithstanding this optimistic view, the officials of the city wrote to the Empress on February 3, saying: 'There are few people here; no Indians, and blacks are expensive. Let the people bring negro slaves, paying the export duty at this port.' Again, in April, they wrote: 'Everybody is in debt, on account of buying negroes on credit in the hope of getting gold, and then not getting it. Many are in jail, and others have fled to the woods, to escape their creditors.' The officials sent 5000 pesos royalty in 1533, and only 6500 pesos in 1534; representing a production of ten times those amounts.

In 1535 only 5000 pesos were sent to Spain as the royal tenth. This increased to 10,000 pesos in 1536; and to 12,000 pesos in 1537. In 1536 Sedeno finished a lively campaign against the Caribs, and then started toward the South American coast. It is quite possible that a large part of the royal share of gold was expended in fitting out the expeditions against the Caribs, which would account for the small amount sent to Spain. In 1538 gold mining declined to such an extent that we may almost consider the industry abandoned from that date. The officials wrote in July of that year to the effect that several veins of silver-bearing lead ore had been discovered, stating that if the tax on all metals except gold was reduced to one-twentieth or to one-fiftieth, and the tax on gold continued at one-tenth for ten years, the search for veins would be continued. They further recommended that sugar planting be encouraged.

In January, 1539, the melting of the entire gold product for the preceding ten months yielded only 30,000 pesos. Some silver or lead ore was taken out of the veins which had been discovered; but after an unsuccessful attempt at smelting it they concluded to abandon that line of work until the arrival of an expert. It is doubtful whether any expert has ever made a thorough investigation of these lead deposits, which appear to be situated near the headwaters of the Rio de la Plata, and not far from the trail which joins the towns of Cagunas and Patillas.

The island remained in a miserable state until about 1550, when the sugar industry began to be important. In 1552 the Contador, Luis Perez de Lugo, wrote to the Emperor that because of the sugar mills very little gold was taken out. In 1554 the officials of the island repeated this assertion, adding that it would be well to order that each proprietor should put at least fifteen negroes to work in the mines. No definite record seems to have been kept of the gold production of the island from 1538 to the present day. Mining was carried on very irregularly, and it is probable that the payment of the royal tax was avoided whenever possible. A conservative estimate of the average annual production has been made by Manuel Victor Doncevel, of Ponce, P. R., who places it at from 6000 to 8000 pesos per year. The existence of the placer deposits has been recognized by all the historians, though the great majority of comparatively recent writers have either absolutely ignored or have denied the fact that deposits of gold in veins were discovered, and that the Spaniards actually worked them until the news of Peru, Honduras, and other lands drew away the experienced miners; just as the news of the rich mines of California drew the miners from Georgia and the other Southern States which had up to 1848 produced the greater part of the gold mined in the United States.

In Table 2 is given a recapitulation of the gold production of Porto Rico up to and including the year 1538, the total for the thirty years amounting to practically six million dollars.

The annual report of the Director of the United States Mint shows that the production of gold in the United States for the years from 1792 to 1848, inclusive, or from the establishment of the U. S. Mint until the discovery of the rich gold deposits of California, was $24,537,000; or an average annual production of only $438,160 as against an average annual production of $198,818 for thirty years of sixteenth century mining in the little island of Porto Rico.

**Determination of nickel in ores.** According to Pozzi-Escot, may be made with accuracy by the following method, even when Co, Fe, or Mn are present. In a solution of the ore alkaline-earth metals are first separated by use of (NH₄)₂SO₄ solution. The filtrate is then concentrated, and to it is added a large excess of (NH₄)₂MoO₄ in saturated solution, and also some NH₄Cl. The mixture is heated to 80 or 90°C for some minutes, then stirred frequently for an hour until cold, the cooling being preferably effected by use of ice. All of the Ni₃ is thus precipitated as nickel ammonium molybdate together with most of the iron. Filter, wash with NH₄Cl saturated solution and separate Fe by NH₄Cl with NH₄OH. In the filtrate the Ni can be separated for weighing by any one of many known processes. Grossmann and Schlick assert that the reaction (which is not new) does not cleanly separate Ni from Co, some insoluble compounds of Co being always formed. Hence it is inapplicable as a test for Ni in Co salts, or in presence of that element.
MILLING AND CYANIDE PRACTICE, SAN PROSPERO MILL, GUANAJUATO.

Written for the Mining and Scientific Press by J. S. Butler.

The San Prospero mill belonging to the Mexican Milling & Transportation Co., is situated on the outskirts of the City of Guanajuato, Mexico. The mill was built for the purpose of treating custom ores and has been in operation since November, 1906. During this period it has milled and treated the ores from various deposits within the immediate neighborhood of Guanajuato. The results obtained formed the basis of operation for the San Prospero mill and may be taken as an example of the treatment of silver ore in this part of the country. The mill is constructed on a hillside having an average slope of 24°. The ore after entering the bins at the top of the mill is not again handled by physical labor but returned for treatment in any particular. The motive power is entirely electric, being furnished at 15,000 volts, alternating current, and transformed to 440 volts for the motors.

A 275-ton storage bin, 90 ft. behind the mill proper, feeds by gravity to a No. 3 McCully crusheer. This discharges onto a 16-in. Robins belt, which moves across the sample-patio to a cross-belt above the battery ore-bins. These bins have a capacity of 375 tons and are filled by means of a Robins automatic distributor. Each conveyor-belt is operated by a 3-hp. Westinghouse motor, and the ore is fed to the batteries by Davis automatic feeders. The stamp-mill consists of forty 1050-lb. stamps, dropping 7 in., 102 times per minute. The stamp-guides are of the El Oro solid pattern. The cam-shafts are the Blanton pattern, the bearings being turned to receive the shaft, thus eliminating the necessity for babbit-metal. The mortars weigh 7500 lb. each, and are anchored to concrete foundations with 1¾-in. anchor-bolts. The battery-timbers are of Oregon pine and are bolted to cast-iron shoes, which in turn are anchored to the mortar blocks. The battery-timbers are also attached to the sills of the ore-bin, allowing the weight of the ore to aid in steadying the battery-frame. Tyler crimped-wire slot-screens are used in the batteries. The stamps are in units of 20, each being driven by a 50-hp. motor. No amalgamation is done, the pulp flowing directly to the concentration plant.

The concentrating plant consists of four classifiers, eight No. 3 Wilfley tables, sixteen cement-tables, and one vanner. The cement-tables were introduced by J. B. Empson, his idea being to procure a cheap efficient means of separating very fine sulphide, which it was found impossible to detain on the Wilfley tables. These cement-tables are 4½ ft. wide by 27 ft. long, with a pitch of ½ in. per foot. A thin layer of concrete is laid on a wooden platform, and a layer of cement placed above this. The cement is scratched, before setting, to form riffles. This table has proven more satisfactory than canvas, and much cheaper.

The overflow from the cement-tables goes directly to the slime plant, while the sand and concentrate retained are washed into collecting-boxes, and cleaned on the vanner. The sand tailing from the Wilfleys are conducted to the thickening cones at the head of the tube-mill. There are two of these cones 30 in. diam. and 36 in. deep, in which the pulp is thickened to three parts water to two parts sand. The tube-mill is 14 ft. long by 5 ft. diam. It is driven at a speed of 29 revolutions per minute by a 35-hp. motor, lumps of hard ore being used for grinding instead of pebbles. From the tube-mill the pulp flows to the separators 8 ft. diam. by 8 ft. deep, supplemented by four small cones, the underflow going to the sand-collecting vats, and the overflow to the slime-plant.

The sand-plant consists of two steel sand collecting-vats 26 ft. diam. by 6 ft. deep, and six leaching vats of the same dimensions. A Blaisdell distributor is used to fill the collecting-vats, the slime being drained off through a central slot-box overflow, and pumped back to the separating cones. A Blaisdell excavator and Robins belt system is used for charging and discharging the sand-vats. In connection with the plant there are two storage-vats of 90 tons capacity each, situated 15 ft. above, for the strong and weak cyanide solutions used in sand treatment.

The slime-plant consists of two steel slime-thickeners 26 ft. diam. by 12 ft. deep, six slime-treatment vats of the same size, three masonry collecting-vats, and the installation of a 60-frame Butters filter for the washing and thickening of slime-pulp.

The slime-thickeners are above the treatment-vats and are discharged by means of goose-necks into a launder running the length of the slime-plant. The pulp in the treatment-vats is agitated by revolving arms through which air is continually blown. The arms are driven by a worm-gear at three revolutions in each two minutes. The pulp is further agitated by 6-in. centrifugal pumps, one being installed for each two vats. The three masonry-vats mentioned above are used to retain slime, wash water for the press, and to receive the slime left in the press after the cake is made. The weak solution from the vat above the sand-plant is used for slime washes as well as sand-washing after treatment. Above the zinc boxes are two sand-filters for clarifying the weak solution, and a storage-vat for strong solution. Each vat feeds to the boxes in the zinc room, the tailings being run to separate storage-vats outside. The precipitation boxes each contain five compartments, 36 by 36 by 36 in., with angular bottoms, the screens being 6 in. from the bottom, allowing 30 in. space for zine. Two-inch underflow valves connecting with a launder carry the precipitate to the sump. From there a Snow pump delivers to a Schrive filter-press above the boxes, so that the drainings flow to the head of the zinc-boxes, avoiding any chance of loss. There are four melting furnaces fitted to receive a No. 300 graphite erusible.

The pump-room contains two tailing solution sump-vats, one for strong and one for weak solution, and one mill-supply vat which receives the overflow from the slime-thickeners and as much strong or weak tailing-solution as may be necessary. Two Aldrich triplex pumps 8 by 9 in. deliver from the mill-supply
The sand shows the following on screen-analysis:

<table>
<thead>

</table>

Averages on the same charges show that approximately 70% of the extraction is made from the sizes through 40 and on 100 mesh, the extraction of the material held on 150 mesh being slightly lower, and of that on 40 mesh, on 200, and through 200 mesh being quite low.

The slime flows to the thickeners above the slime plant and is delivered with 70% moisture through receivers is charged 'dry,' that is, de-watered, into the treatment-vats. Here 30 washes of strong solution of 0.32% KCy are applied, followed by 20 washes of weak solution of 0.15% KCy, and 5 washes of clear water. Each wash of 10 tons of solution requires from 3½ to 4 hours to pass through the charge. The sand is automatically discharged after the last wash.
Butters filter, with fresh water. The rate of extraction in the slime-plant is shown by the accompanying curves plotted from results obtained during two months' run.

The slime-pulp, with the last wash of clear water, is drawn from the masonry vat through the filter-press, the solution flowing to a sump. The cake is formed in 40 minutes, after which time the remaining slime is returned to the masonry vat and the cakes washed with clear water for 30 minutes. The wash-water is returned to the supply tank to be used again, until it contains sufficient metal in solution to be sent to the zinc-room. The cakes are finally discharged with fresh water. From 20 to 22 in. vacuum is used on the press, and the cake formed is from 0.6 to 1 in. thick. The filter-leaves are soaked for five hours in a 1 to 1.5% acid-bath, before being set. The cycle of operation of the filter for five tons of slime is as follows:

</tbody>
</table>

The strong solution from the first washes of the sand flows to the supply-vat at the head of the zinc-boxes, while the weak solution from sand, slime, and filter-press is run to a sand-filter on the same level. The zinc-boxes are fed from these supplies, the solutions going through separate boxes and the tailing flowing into the separate vats in the pump-room. The flow of the weak solution is regulated to 5 or 6 tons per hour and the strong solution to 2½ tons per hour. Clean-ups are made every 10 days, the zinc-shaving being thoroughly washed and transferred. When all the precipitate is sluiced to the sump it is pumped through the Schrever press, and the cake is thoroughly dried with hot air. It is then flushed and charged 'loose' into the crucibles.

The sodium-cyanide is added in the sump-vats, and the strength of the weak solution and the mill solution regulated by pumping from the common supply. An absolute regulation is obtained by this method. The consumption of cyanide for the past three months has been 0.8 kg. per ton of ore milled, and the zinc used 0.37 kg. per ton. A small amount of lead acetate, 0.07 kg. per ton, is supplied to keep the solution from fouling. A curve is added showing the percentage of extraction throughout the mill, due to the new system of crushing in cyanide solution.

By an examination of this sketch, it will be seen that the extraction of metals in the mill before the pulp reaches the cyanide plant is as follows:

**MINERAL WEALTH OF NORTHEASTERN OKLAHOMA.**

The demand for information concerning this new State has resulted in the publication of data by the U. S. Geological Survey in Bulletin 340, which forms Part I of 'Contributions to Economic Geology, 1907.' The area covered by this report is a strip extending 83 miles in an east-west direction and 104 miles from north to south, including the northeastern part of the Creek Nation, practically the whole of the Cherokee Nation, and all of the Seminole, Wyandotte, Ottawa, Shawnee, Modoc, Peoria, and Quapaw reservations.

The lead and zinc deposits now known occur only in the northeastern part of the area covered by the report, and the districts where mining has been carried on, or where the indications have encouraged extensive prospecting, are described in chronologic order. Areas that have yielded oil and gas are briefly discussed and are outlined on the geologic map. The most productive areas are the Alluwe-Coodys Bluff or 'shallow sand' field, the Bartlesville or 'deep sand' field, and the Glenn 'pool,' near Kiefer. Smaller pools lie between the Bartlesville and Glenn fields, in line with them, at intervals so close as practically to constitute a continuous field from Kiefer to the Kansas line. New but promising areas are the Delaware, Hogshooter, and Morris-Baldhill fields. Most of the coal beds of the district are thin and not of great extent, but several have been worked to supply a market that is more than purely local. The rock formations of this portion of the State include an alternating series of limestones and sandstones, with intervening shale, the whole dipping gently north of west. As the limestones and sandstones are harder than the shale, and thus offer more resistance to weathering, they tend to form long gentle westward slopes, with steeper eastern slopes of shale, the harder rock coming to the surface along the crest of the ridge. Where the limestone has been protected from weathering by a thin covering of shale the essential materials for cement are found in favorable relationships. Where, in addition, adequate supplies of fuel, especially natural gas, and good transportation facilities are available, the climax of advantageous position for cement manufactures has been reached. The area is well supplied with building stones: limestone, sandstone, and granite. Rock suitable for supplying small local demands can be found almost anywhere within a mile or so of the place where wanted. Surface clays are suitable for the manufacture of common brick, and shales that are adapted for making vitrified brick are also abundant.

Phosphate deposits are always bedded, and so may be located as placer claims, under the same conception as limestone or shale for cement-making. In neither case is the rock to be considered in the light of structural material, which was the intent of the law in its reference to locations of stone for quarrying. The material is required for what it will yield as a chemical substance in the manufacture of commercial fertilizer.
WHEN LABOR UNIONS co-operate with employers in scientific enquiries tending to determine conditions of mining practice which shall simultaneously promote safety and economy, one may begin to look forward to a time when these associations shall prove an important aid in doing the world’s work more efficiently and honestly. There would seem to be no valid reason why the labor union should not be a welcome assistant to the capitalist, while promoting those aims which are professionally at the bottom of all such organizations—enhancement of the dignity and rewards of labor. The concrete case inspiring this brief homily is the appointment of a powder commission in the State of Illinois to settle all disputes relating to the use of powder underground, including the investigation of shot-firing devices, the making and grading of powder, and many technical questions relating to safety and efficiency in coal mines. On this commission the labor union has equal representation with the operators. In Indiana recently 52 members of a miners’ union were expelled for bringing action in the matter of a fine assessed against them for causing a ‘stampede strike,’ and the union as an organization paid the fine which was levied under the terms of the contract. Evidently the age of reason is dawning in the Mississippi valley.

Harmony and Good Sense at Goldfield.

A NOTABLE illustration of the superiority of common sense over obstinate determination to get the ‘pound of flesh’ nominated in the bond, is furnished by the agreement reached between the litigants in the celebrated case involving the Goldfield Consolidated Company and the Jumbo Extension at Goldfield, Nevada. Owing partly to the complex mineralization, and partly to the inherent difficulties of the so-called ‘law of the apex,’ it was evident that the proceeds of the mines would be wasted in an endless legal contest unless technicalities were brushed aside and the questions at issue settled by a practical adjustment in the light of geological peculiarities not provided for in the existing statutes. The compromise is likely to exert a far-reaching influence, lessening the esteem as an essential feature of a mining claim in which the extra-lateral right has been widely held. The principle of restriction of proprietary rights to a vein within the vertical side-lines of the claims has been accepted as a controlling factor in the agreement reached, and yet, as usually happens in the making of compromises, some inconsistencies are embodied in it. The lode in the Mohawk dips toward the east, and the Wedge fractional claim, lying adjacent on that side, is deeded to the Goldfield Consolidated; this
company owns the next two claims, which are adjoined by the Polverde, belonging to the Jumbo Extension Company. The right to that portion of the vein lying within the vertical side-lines of the Polverde is conceded to its locators, but the Goldfield Consolidated will mine and treat the ore on joint-account, and no extra-lateral rights are acknowledged beyond the east side-line of the Polverde.

A simple vertical side-line agreement has been likewise reached between the Goldfield Consolidated and the Combination Fraction, as far as relates to that claim. In this instance the right to the continuation of the vein on the dip eastward from the Combination Fraction remains vested in the Goldfield Consolidated through its ownership of the adjoinging Jumbo claim. In the case of the Vinegorone fraction, the same arrangement applies as in that of the Polverde, except that the rights of the Goldfield Consolidated are recognized as becoming re-established on the vein where it dips beyond the Vinegorone side-line into the Laguna claim. The extra-lateral principle, as laid down by the law of 1872, is here widely departed from for the sake of settling present difficulties, but the effect of the provisions for extravagation under extra-lateral rights as finally interpreted by the courts, gives rise to the interesting question of what right there might be to follow the vein indefinitely on the dip beyond the most easterly side-line of the Goldfield Consolidated property, since no apex exists on the claim where the right becomes re-established. Such a dispute might be adjusted by a further application of the commonsense principle which prevailed in this happy settlement of difficulties. The example set will undoubtedly be followed elsewhere, and the establishment of such precedents may easily blaze the way for modifications in the Federal statutes relating to mines. An agreement out of court also accepting the vertical side-line limitation has terminated the contest between the West End Consolidated and the McNamara Mining companies at Tonopah. A spirit of good-will seems to bubble up freely as soon as definite boundaries to property are substituted for the uncertain meanderings of titular rights into a neighbor’s domain.

**Mexican Mining Law.**

It is our privilege to present in another column a clear explanation of the scope and aim of the proposed revision of the Mexican mining statutes, communicated to us by the author of the measure, Mr. Ciegaro Molina, Secretary of Fomento of the Republic of Mexico. This statement is one which should allay the apprehensions of capitalists financially interested south of the Rio Grande, and should encourage those contemplating investment in enterprises based upon utilization of the natural resources of our sister republic to repose greater confidence in the Government than would be possible were it careless of the ordinary safeguards adopted by the leading nations of the world. The excessive liberality of the Mexican Government in regard to legislation favoring foreign capital and in the bestowal of cessions and special privileges has been criticised perhaps more severely by those outside of the Republic than by its own citizens. Tendencies in the past were distinctly toward favoritism, involving the evils inherent in a system admitting of discrimination. Foreign companies could plead special consideration of rights based upon powers conferred by law in the country of their origin. The machinery of the diplomatic service has been repeatedly called into operation to adjust difficulties of a private character that would have been settled by ordinary judicial process except for the complications arising out of the peculiar status of alien corporations.

Special inducements were needed to allure capital from abroad after decades of romantic and highly uneconomic political vicissitudes. The construction of a great self-conscious, self-respecting nation out of multitudinous warring factions was a cyclopean task. Few men in any country or any age could have done it in thirty years. No advantages of politico-geographic position were available for President Diaz whereby he could turn mutual jealousies of neighboring powers to account in forwarding his schemes of national aggrandizement. Mexico was isolated, touching the United States along what was, until recent years, a wild frontier of sparsely-peopled desert, with turbulent petty states to the south, and bounded east and west by long stretches of ocean. The resources of the country were imperfectly known, while stable governmental authority was believed impossible. Under such circumstances the invitation to foreign capital required the offer of advantages commensurate with the apparent risk involved. Among these were provisions of law admitting foreign corporations under terms which meant practical recognition of the right of appeal to diplomatic intervention for the settlement of a large class of difficulties. Such a condition necessarily leads to complications and unequal justice. Mexico has progressed to a point where, in the opinion of her statesmen, she may presume to adopt the regulations prevalent in other self-reliant countries. It is natural that such manifestations of an independent spirit should meet with disapproval by those who had come to consider extraordinary privileges as an inalienable right. The effort to attribute the proposed changes in the mining law to a spirit of animosity toward the foreigner is manifestly without warrant. The Mexican has borne the humiliation of the war of 1848 with a grace worthy of profound admiration, and while some lingering distaste for the American may find occasional expression by hot-heads, the sincerely cordial feeling of the people and the Government has been confirmed in too many ways to be distrusted. Such clamor is discreditable to those who make it. The facts do not sustain the criticism.

An examination of the provisions of the new articles in the project of law drawn up by Mr. Molina discloses no attempt at embarrassing foreign capital in the Republic. The law cannot be made retroactive, so that vested interests will remain undisturbed. There is no restriction upon the organization of companies by foreigners under the laws of
OFFICIAL STATEMENT CONCERNING THE
PROJECTED REVISION OF MEXICAN
MINING LAW.

CORRESPONDENCIA PARTICULAR
DEL SECRETARIO DE FOMENTO.

MEXICO, D. F., July 20, 1908.

Editors MINING AND SCIENTIFIC PRESS,
San Francisco, Cal.:

Sirs—Referring to your kind favor of June 29, I take pleasure in giving you the information you desire regarding the clauses governing foreign rights as embodied in the proposal for the new mining law for the United States of Mexico, and which has been of late under discussion in the press.

The project contains two fundamental rulings on the matter as follows: the first establishes as a condition for permitting foreigners to acquire mining properties in the frontier States and Territories, that they shall previously obtain the permission of the Government of the Republic; while the second prohibits absolutely all foreign companies to acquire mining properties in any portion of Mexican territory.

The first ruling is not an innovation in the laws of the Republic, for there is extant the law of 1856, which exacts as a vital requirement the permission of the Government of the Union, in order that foreigners may acquire landed properties of any kind whatsoever, in any zone within twenty leagues parallel to the frontier line with any foreign country. The steady application of this law has not in practice presented the slightest objection, and all foreigners who wish to take possession of properties in the said zone, apply to the Federal Government for the necessary permission, which is never denied them whenever it appears from the report of the higher State or Territorial authorities that the applicant is in good standing and worthy of confidence.

By the new ruling in the project for the new mining law, it is proposed to make applicable to all the States and frontier Territories, but making mining properties only subject thereto, the said condition or restriction established by the law of 1856.

It is not difficult to justify the reason for said ruling if we consider that in the greater part of the frontier States of the Mexican Republic, the prospect of rapidly acquired riches through mine development, attract large numbers of persons of adventurous spirit and questionable character, such as always infest the frontier lines between two countries. It is imperative that the authorities should exercise due supervision over this class of persons, who frequently incite to conflicts and grave international complications, owing solely to their utter lack of principle; and of such, unfortunately, we have not a few examples in this country. For these reasons, therefore, it is, in my opinion, necessary to extend the zone within which foreigners may acquire mining properties, only after having secured from the Government permission for the purpose, which only means that foreigners must merely show cause that they are reputable persons capable of acquiring.
mining properties without becoming a source of trouble to the State.

If we compare the condition just referred to with the Federal laws which obtain in the United States, and which exact either citizenship or at least the explicit purpose to secure the same in order to allow a private party to become owner of a mining property within the nation’s territory, we must conclude that the new project cannot be accused, in this respect, of illiberality and undue restriction.

The existence of all companies, whether commercial, mining, industrial, etc., in every nation, really takes root from a legal conception. Said companies cannot possibly exist if the law does not authorize their creation, and unless the law-giver by whose permission said companies come into being, does also affix the limits of their activities. It may surely be affirmed that in these respects all the laws of civilized nations are in accord.

Granting, therefore, the preceding principle, the legislator of any given country is simply exercising an axiomatic right in not permitting ownership of landed properties within the State’s jurisdiction, to such companies, corporations, or moral entities which owe their existence to the act of a foreign legislator, and whose rights and faculties depend upon the will of said legislator. The laws of Mexico, in accordance with those of many other countries, establish that the capacity of parties to own landed properties within Mexican territory is governed by the laws of Mexico, regardless of the nationality of the individuals in question. Therefore it is but an application of said principle to exact that all companies, or corporations, shall be organized in accordance with the laws of Mexico before they shall be empowered to acquire ownership within the Republic.

Therefore the right of the Mexican legislator to establish the restriction aforesaid would seem to be indisputable, as is also, in my opinion, the expediency of the measure. It is obvious that the Mexican authorities can on many occasions be confronted with serious obstacles to the proper enforcement of the laws, even in matters pertaining to territories within their jurisdiction, whenever the owner of the said lands shall escape all application of the law due to his owing his legal existence to foreign laws over which the Mexican authorities possess no supervision whatever. Let us take, for example, the formation of a ‘trust’ of the foreign corporations owning mining properties in Mexico. If for political or economical reasons it became necessary to the national interests to limit the abuses, or restrict the methods of said ‘trust,’ the Mexican authorities would encounter serious obstacles to the carrying into effect of remedial measures necessary to the nation’s welfare, owing to the fact that the companies forming the ‘trust’ would be beyond the jurisdiction of the laws of Mexico. Whereas, if the said companies should be organized under the laws of Mexico, the legislator, the Government, and the Courts of this Nation would be enabled to exercise their legitimate functions, restraining or preventing any abuse of the powers possessed by enormous consolidations of capital, such as are constantly disturbing public feeling in the United States, and occasioning serious harm to numberless worthy and legitimate enterprises which would be powerless to defend themselves against such ruthless and omnipotent competitors.

Otherwise foreign capital, even with the restriction referred to, will be at liberty to invest in Mexico, subscribing to the shares of companies organized under the laws of Mexico. The prohibition merely applies to the acquisition of mining properties by foreign corporations, but in no sense to the investment of foreign capital in mining companies organized under the laws of Mexico. Neither is it forbidden to individuals of foreign nationality or citizenship to organize in Mexico mining companies, as these would be Mexican, being organized in accordance with Mexican law, even though all the individuals forming the company or owning shares therein, should be foreign. Neither should we lose sight of the fact that the citizenship of the foreigners comprising the said companies would be preserved inviolate, however important might be their interest in Mexican companies.

Finally, foreign companies shall always be empowered to work mines in Mexico, under lease or other arrangement, which does not entail the transference of ownership. This practice is constantly resorted to in the working of properties within the twenty-league frontier zone, because in virtue of the interpretation which has been given to the law aforesaid, no foreign company can acquire ownership of mining or real estate within the said prescribed zone. Nevertheless, within said zone, and on the frontier with the United States, there have been developed with exclusively foreign capital, mining claims of great importance, which have not found the restrictions mentioned any hindrance to their successful operation, and which are worked by companies organized under Mexican laws.

It is understood that foreign companies at present working mines in Mexico shall not be deprived of the rights under which they have been operating. As in the case of the American Constitution, that of the Mexican Republic contains a clause which forbids any law from taking effect retroactively. Consequently, foreign companies owning mines shall continue to own them, though for the future they would lose the right of acquisition.

It would seem in order to add that the Mexican Government is greatly desirous of encouraging the investment of foreign capital in the Republic. The Government recognizes that to foreign capital is due a large share of the present national prosperity. Yet I, personally, as also many other persons of standing in the Nation, believe that it is most essential to the general welfare to exercise some supervision over the said capital, and this is the object of the project of law which I have here analyzed. The allegation that the Mexican Government is not well disposed towards foreign capital is utterly false, and cannot be dictated by the policy pursued by the actual Government for many years. As for what concerns me personally, I would add that I have followed, in the Department of National Development, the precedents established by my predecessors. I am glad to grant all facilities and information to foreigners that may enable them to effectively transact their business, provided, of course, that their purposes be serious, and their methods consistent with law and morality.

Faithfully yours.

O. Molina.
Personal.

ALBERT BURCH has returned from placer county.
R. J. LINTON, of New York, is in Los Angeles.
Roger C. KNOX was in San Francisco from Tonopah.
Edward K. Judd is examining mines near Silverton, Colorado.

DOUGLAS WATERMAN has returned to San Francisco from Antofagasta, Chile.

Mark B. Kerr has returned from Tonopah and will make his headquarters in the Mills Building.

J. H. FENNESSEY, president of the Mine & Smelter Supply Co., has returned to New York from Denver.

H. S. KENNEY is now metallurgist to the Penhalonga Proprietary Mines, Ltd., Rhodesia, South Africa.

Jos. C. ELMAN, of Los Angeles, was in San Francisco on his way to examine mining property in Plumas county, California.

WILLIAM A. POMEROY has been appointed general manager for the Lautre Mining & Smelting Co., at Santa Maria del Oro, Durango, Mexico.

E. E. BRE提倡TON, of the Bretherton Metallurgical Co., has gone to Redding, California, in the interest of the Redding, Afterthought & Northeastore railway.

H. C. CUTLER, chief engineer and acting manager for all of the Nixon & Wingfield holdings, is making a tour of inspection of all the company's possessions in Nevada and eastern California.

Horace Y. WINCHELL has resigned as chief geologist of the Great Northern Railway Co., to enter into general practice as consulting mining geologist, with offices at Minneapolis, Minnesota.

C. H. B. PALMER has been made general manager of the Guajalito Development Co., Guajalito, Mexico, and associated concerns. He will also act as consulting engineer for the Esperanza Mining Co. in El Oro district, Mexico.

Obituary.

FREDERICK S. HARRIS died at San Diego, California, on July 17, after a siege of 18 weeks with typhoid fever. At the time of his death Mr. Harris was manager for the Kansas City-Goldfield Mining Co., at Goldfield, Nevada. Previous to that he had been associated with mining enterprises in the San Juan region of Colorado and in Mexico. He represented both W. C. Andrews and W. G. Carroll & Co. as mining engineer for many of their enterprises in Mexico and Central America. He was born in Chicago, October 22, 1853, and maintained an office in that city to the time of his death.

ANICETO GARCIA MENOCAL, long in the public eye as the chief engineer of the Nicaragua Canal, one of the most brilliant of America's civil engineers, died July 20 in New York. Mr. Menocal, the son of Gabriel Menocal, a Cuban planter, was born in Havana, September 1, 1839. He came to the United States in 1857 and five years later graduated from the Remsseilier Polytechnic Institute, at Troy, N. Y. On receiving his degree as civil engineer, Mr. Menocal returned to his native city, where, in 1863, he was made assistant chief engineer of the Havana water works. His work attracted attention, and in 1870 he accepted an offer as engineer in the Department of Public Works of New York City. He stayed there two years and left to become chief engineer in the Navy Department. In the service of the Government he attained distinction. He acted as chief engineer on all the surveys for establishing the practicability of a ship canal at Panama and Nicaragua, was chief engineer of the Maritime Canal Co. of Nicaragua, and in 1887 prepared plans and estimates of cost for a ship canal through Nicaragua. Mr. Menocal was sent to Paris by President Hayes as a delegate to the Canal Congress in 1879. For his work there he was made chevalier of the Legion of Honor by President Grévy.

Arizona.

The directors of the Willie Rose Mining Co. held a meeting this last week and decided to resume work on the property 18 miles north of that place. F. O. Bacon has been appointed superintendent, and he expects to have operations under way early in August. —The new shaft at the Savage is now down about 115 ft., and the first station is being cut, preparatory to opening up the 100-ft. level. On this level a cross-cut will be run in a southerly direction to the orebody, which is not very far away.

Mohave County.
The Grand Bay mine, near Chloride, has purchased a small hoist and will use it in sinking a shaft to a depth of several hundred feet.—Reports from the mines of the Arizona Southwestern Copper Co. indicate that a large flow of water has recently been struck, and as a consequence operations have been suspended pending the arrival of a pumping plant. In the meantime a new shaft will be started at the Pittsburg claim of the group.—It is possible that the Gold Road M. & E. Co. will change its motive power from gasoline to electricity and also remodel its mill. J. de Salmur, of Goldroad, is superintendent.

Tavapai County.
Plans for the re-opening of the old Stonewall Jackson silver mine in the Globe district, and for the exploration of adjacent claims, numbering 32 in all, have been completed. V. Y. Smith is president of the new McMillen Silver Mining Co. The existing 120-ft. shaft will be sunk to at least 300 feet.

Yuma County.
The Harqua Hala, in the Ellsworth district, 8 miles south of Salome, has suspended operations, but will resume on a larger scale September 1. The company is making preparations to install a large cyanide plant to treat tailing. It will also start a new working shaft.

California.

Inyo County.
Work is about to be resumed on a small scale on some copper claims 12 miles northwest of Mammoth, on Shady creek, the original location of which was made by J. W. Douilliard. The company is a Chicago concern called the Cascade Mining Co., in which the same people are interested that have taken hold of the Casa Diablo. The property is in one of the richest parts of the Sierras, at the headwaters of the San Joaquin river, and it will cost a large amount of money to get it into shape. The claims are 15 miles in an air-line from the end of the Bodie and Benton road at Mono mills.

Nevada County.
(Special Correspondence).—J. W. Jaquish and E. P. Hill, large owners in the Moryedena mine, are inspecting the property with a view to the early resumption of activities. A promising vein lies at the bottom of the shaft. —The adit being driven at the Leduc mine is in 125 ft. Progress is slow owing to the hard ground. A compressor will be installed in the near future.—Only two shifts are working at the Brunswick. No report has been given out by the officers, who recently inspected the property.—A force of men are cutting a station at the $3000-ft. level in the Central shaft. Lower stations will be cut within a short time.

The insurance rates on local mining properties have been reduced. This means a considerable saving for several companies. —Arrangements are under way for the resumption of activities at the Gold Flat mine. As soon as matters can be adjusted the mine will be unwatered and the shaft sunk to considerable depth. It is reported that the Gold Flat people are desirous of securing the Pittsburg, an adjoining property. Both mines could be worked through one shaft.

Grass Valley, July 27.

Shasta County.
The output of the Quartz Hill mine will be greatly curtailed by the Mammoth Copper Co. on account of the heavy shipments coming in to the mines in the Utah mines of the United States Mining Co. Shipments of from 100 to 150 tons per day are being made because of the injunction prohibiting the smelting of sulphide ores at the Utah smelter. The Utah ores are especially well adapted for fluxing ores and take the place of the Quartz Hill ore at the Kennett smelter.

Sierra County.
The Keystone mine, near Sierra City, has been closed down for a short time in order that an auxiliary electric plant may be installed. The mine employs 40 men.—Work has been resumed at the Gibraltar mine at the head of Cayon creek. A shaft is being sunk in the hopes of striking a gravel channel.—An 18-ft. vein has been uncovered at the Grizzly Consolidated, at Poker Flat, and there are 100 tons in the ore-bin ready to be treated.—A strike of rich gold ore was made in the Twenty-one mine, at Alleghany, last week. The strike was made at a depth of 100 ft. more than any ore in the Tighter, its near neighbor, and for that reason the strike is encouraging.

Siskiyou County.
At the Tennent mine, on Long gulch, near Hawkinsville, at a point less than 100 ft. from the old shaft, a blind vein has been uncovered which is 30 in. wide. In sinking seven feet on the vein it widened out to 42 in. Indications from panning led to the belief that the ore is quite rich.—A Chinese company is just finishing a wing dam preparatory to working one of the rich bars on the Scott river, at the mouth of the old town of Scott Bar. The Sheba mine, on Patterson creek, for several days ran with a few men doing development work, as it was thought the orebody was giving out. Last week they uncovered a large body of very rich ore in the shaft and now have a large crew steadily at work. The mill is running day and night. The company is preparing to sink a shaft 1000 ft. deep on the orebody.

Colorado.

Clear Creek County.
(Special Correspondence).—The Empire Railway Mining & Milling Co. has recently been incorporated, and will take over the Silver Mountain mill, at Empire, which will be overhauled and the capacity increased from 25 to 50 tons per day. It has water-power rights on Clear creek and Middle Clear creek which will be developed, and the power used for operating the mine and mill, and also furnished to the operators of the district. It is understood that an electric tram-line from the mine to the mill will be put in. The Silver Mountain mine, of which this company is the owner, has a large amount of development work already done through shafts and laterals. Compressor and drills will be installed.—A number of Eastern capitalists have become interested in the Everett and Lebanon mines, on Republican Mtn. It has been decided to drive the Everett adit about 400 ft. to intersect the Elijah Hice vein. Work will also be started in the advance of the Lebanon adit to gain greater depth. Work on the Smith & T. Co. has been suspended pending a change of bonds, but shipments have been made. The ore is a heavy lead, carrying wire-silver in liberal quantities. Maxim Bros. of Georgetown are in charge of the work.—A 30-hp. Garden City fan has been installed at the Capital adit, the connection having been made this week. The Capital M. & T. Co. controls nearly 2000 ft. lying ahead of the present breast and the hoist will be turned forward to intersect the series of veins as controlled. It is estimated that an average net production of $75,000 is being made monthly from this property. It has virtually been decided to construct another mill with a capacity of 125 tons daily. Whether a separate plant will be built or another section added to the one now in operation will be decided in a few days, or as soon as Mr. Cooper returns from Pittsburg, where he has been in consultation with the officers of the company. Such vast
reserves of mill dirt are now exposed in the working of the Aetna vein that some way must be found for taking care of the product. A new strike is reported from the stope being carried at the extreme west of the Aetna drift, a body of heavy lead ore having been uncovered that is from 2 to 5 ft. wide, the assays of which give $15 per ton. The material will be shipped direct to the smelters.—A number of stockholders of the Windlender Metais Co. are in camp making an examination of the holdings. Pins are now being perfected for extensive operations and work will be in full swing by August 1. Power-drills will be installed at the Huckleberry workings, power to be secured from the electric plants of the United Hydro Electric Co. D. F. Sprague is in charge.—R. Fisher is sending out occasional shipments from the Hercules, the ore being worth from $60 to $80 per ton. A new adit has been started, the heading of which has now penetrated the mineralized zone, a body of iron having been passed that is 2 ft. wide. Within 50 ft. the adit will cut directly under the shot exposed in the upper workings.—E. M. Moser, of Idaho Springs, manager of the Butler mine, has started excavation for a modern concentrating plant. This operator has secured the services of J. G. Roberts, an experienced mill man, who will look after the building of the plant. It is proposed to treat the ore mined from the Butler property, as well as handle custom ore from the various mines of the district.—Work has been resumed on the Tam O’Shanter, which is an extension of the Puzzler. Small streams of good grade ore are being encountered.—The Egan mill, in the Jackson district, has been sold to J. H. McCormick, of Pennsylvania, the consideration being $2500. The plant will be remodeled and tied upon ores from the Gold Leaf mine, of which J. J. Hohan, of Idaho Springs, is manager.—A number of improvements are to be made upon the 49-ton mill, operated by the Honest John M. M. & T. Co. Work in the Black Eagle mine has resulted in immense bodies of ore being exposed, and for this reason the size of the mill is doubled. At present a new Idaho Springs, is manager. Work has been resumed in the breast of the Honest John adit, the bore being in 2100 ft. The Marysville vein will be intersected within 75 ft.—The McClellan adit, which is exploiting the Freelead section, is now over 7000 ft. long, the second longest in Clear Creek county. During the past year the bore was advanced 1000 ft. Since the Freelead vein was reached, and now driving is under way to cut under the shaft workings. With the objective reached a 1200-ft. raise is to be made to drain the old workings.—Wm. Morjan & Co., of Idaho Springs, have taken a lease upon the dumps of the Gem mine. It is reported that a mill will be constructed in the near future.—Moritz Schlegel, of Empire, has started work upon the Surprise group of seven claims, situated at the head of Lyons gulch. On the Surprise vein a body of heavy iron sulphide ore has been exposed that is from 2 to 4 ft. wide.

GEORGEW, July 25.

OURAY COUNTY.

Preliminary work at the Koehler adit is progressing satisfactorily. The transformer, bunk, and boarding houses have been completed and the water system is well under way. Twenty men are at work near the portal. The Koehler is a part of the San Antonio mines and is destined to develop at a greater depth the immense orebodies in which the Carbon Lake shaft has been sunk.—The Brazilian Monitor Mining Co., expects to install a large amount of modern machinery at its property in Poughkeepsie gulch, near Ouray.

BAN JUAN COUNTY.

A contract for 100 ft. of driving on the Grizzly property, in Burrows Park, has been let to Bert Perry, of Lake City,—A force of 16 men are at work at the Tom Moore property, above Eureka, and several cars of high-grade ore is ready for shipment to the smelter at Durango. The low-grade ore will be treated in the Hamlet mill, which is to be erected soon.—The Brazilian Monitor Mining Co., near Mineral Point, is making good progress on a cross-cut tunnel, which is now nearly 300 ft. long, and has 150 ft. more to run in order to cut the vein—The Copper Gulch M. & H. Co. proposes to do some active development on its property in Gray Copper gulch. It owns 67 claims covering about 500 acres of mineralized land. It is reported that a 1500-ft. adit will be driven into Red Mt. E. S. DeGolyer and King C. Gillette are interested.

SUMMIT COUNTY.

A syndicate of Boston people has recently purchased the Carbonate, the Little Tomny, and the Golden Edge groups of claims on Baldy Mt. The consolidated estate consists of 28 claims, a mill-site, and a mill. The new company will let a contract to advance the Golden Edge adit an additional 500 ft. The sale was made by A. H. Phelps, of Denver.

TELLER COUNTY.

The Union Leasing Co., which recently secured a lease on the Deadwood, adjoining the Hull City placer, on Bull hill, has made its initial shipment. After but a small amount of work the company opened up a vein at a depth of 490 ft., from which assays showed the gold content to range from $100 to $200 per ton. The Union Leasing Co. is also operating several other properties in the district with great success.—L. W. Terrill, who recently secured a lease on the Dexter property, on the west slope of Bull hill, will start active operations immediately. He will sink the shaft from the 600-ft. level to a depth of 1000 ft.—The Portland Gold Mining Co. will erect an experimental cyanide plant, with a view to determining whether the ores are adapted to that style of treatment.—The United States Reduction & Refining Co. has announced a new scale of treatment charges for the ores of the Cripple Creek district. The change will affect the skippers to only a slight degree, as the increase over the rates now in effect is small. The changes are as follows:

<table>
<thead>
<tr>
<th>Ore Value</th>
<th>Old Rate</th>
<th>New Rate</th>

TELLURIDE COUNTY.

The Contention mine will soon resume active work. Ketzlub & Junker, who have a lease on the property, have been actively engaged in putting it in shape after the five years of idleness. They have cleaned up the shaft, retubed it, and have purchased a 20-ton Huntington mill. Twelve men will be started at first and the number increased later on.—The Cashin copper mine, in the La Sal mining district, has resumed operation and is working 12 men.

IDAHO.

DONNER COUNTY.

(Special Correspondence).—The old Panhandle smelter, at Ponderay, has been financed by S. W. Gebo, of Montana, and the work of repairing and enlarging is in progress. Sufficient money has been guaranteed to cover debts and provide an operating fund. The plant will be increased to 250 tons per day, ores being contracted for, and as soon as possible the plant will be blown in. Several months of financial failure have retarded work. Money for one year is now assured.

Ponderay, July 25.

SHOSHONE COUNTY.

(Special Correspondence).—The Hecla Mining Co., at Burks, has declared its usual dividend of $10,000. This is at the rate of one cent per share and is the 51st dividend.
declared by the company. The grand total disbursed by the company now amounts to $1,590,000.—Oscar Nord-quiet has resigned his position as superintendent of the mill of the Shoeshone Concentrating Co., near Sweeney at Warder, and has been succeeded by G. Machan. This company was originally formed for the purpose of treating the tailing from the Sweeney mill which handles the ore of the Last Chance Mining Co. It was anticipated that a net return of about $1 per ton would be extracted from the tailing by a close treatment with special machinery. For some time the mill ran at a small loss, but it is understood that recent results have been satisfactory. The mill was designed by W. A. Bradley and embodies many of his own ideas.—An extremely rich strike of nearly two feet of steel galena has been made in the drift in the Mark Cooney group of claims, near the 3000-ft. level, in the Durke. Work on the property was stopped two months ago and at that time the face of the drift showed a slipp. The first shot on the resumption opened up two inches of galena, the next 18 in., and the last about 22 in. The ore is of the highest grade shipping quality.—About August 1 an increase will be made on the force of men on the Interstate Mining & Milling Co.'s property on Nine Mile, and work on the driving of a 3000-ft. adit will be started. This adit is designed to intersect three veins. Work has been carried along steadily on the No. 3 level and a dozen men will be added to the long adit work while development on the upper workings will be continued without cessation. It is expected that the last of the veins will be cut in about a year. The orebodies will be tapped at a depth of about 590 ft., deeper than the lowest developed shaft, and an estimated 5000 tons of ore will be obtained. A meeting of the directors of the Imperial Mining Co. was held in Wallace at the beginning of last week and it was decided to go ahead with the preliminary work on the driving of a long adit. This will be about 2700 ft. in length and will tap the adit at an estimated depth of 722 ft. beneath the present workings, and give a total vertical depth of 2800 ft. A syndicate of Spokane and Wallace men have been formed for the purpose of sinking the work, which is to be done in the outstanding stock. It is the intention of this syndicate to build a wagon road and install machinery. It is estimated that the total cost of the work will be in the neighborhood of $30,000.—The Monitor Mining Co., whose property is near Saltese, Mont., has purchased new machinery to the extent of $7000. This includes a 60-hp. boiler which has been added to the 80-hp. boiler, and a capacity of 40 cu. ft. per minute. It is expected that the installation of the new equipment will increase the mine's capacity fourfold. It is the intention of the management to sink from the bottom of the 400-ft. shaft to the 700-ft. level before any more driving or stopeing is done.—The famous action by Jonathan Bourne, Jr., against the Federal Mining & Smelting Co. has been decided by Judge Dietrich, of the United States Federal Court, at Moscow, in favor of the Federal Company. The case involved the extra-lateral rights of the Ontario lode claim owned by Mr. Bourne. The secretary of the Rainbow Mining & Milling Co. has submitted an annual report. This is to the effect that the main adit has been extended 307 ft., making a total length of 410 ft. Since taking over the group the company has concentrated ore, of which assays show as high as 45 oz. silver, 14% copper, and a small amount of gold. All right of way disputes with regard to the construction of the Idaho Northern railroad have now been settled out of court and it is now expected that the road will be in full working order by Christmas.

Wallace, July 25.

MISSOURI.

JASPER COUNTY.

(Special Correspondence.)—Conditions throughout the mining district are still unsettled, every day noting the closing of mining plants and the re-opening of others. All

the mines in the Oronogo camp are again active and that field is among the busiest in the district. However, most of the mines in Granby are closed and there is little work going on. The Whitehat mine belonging to the Old Dominion Co. closed down last week. The output for the week was normal and the market was more stable than for some time. The total value of the output for the week in the entire mining field was $256,924. One of the latest and best producers in the Joplin camp is now in active lines some 100 ft. west of the city. A large number of strikes have been made of high-grade zinc-blende. About five companies are at work upon leases on the tract. The ore is all found from 35 to 40 ft. and occurs associated slightly with bitumen, which renders the separation difficult. The first strike was made by Hubbard, Cummings & Marr, who struck a rich zinc and lead ore at about 40 ft. from the surface. Another is at the 35-ft. level. One drift has been opened for 30 ft. and a second is started. Collins & Gray, operating a lease on the same land, entered the ore last week at 40 ft. The ore is being cleaned on hand-jigs. East of this company Turnhull Bros. have taken a lease and are engaged in opening an old shaft to catch the same run of ore. A fourth company on the same land is the Blue Bird, which re-opened an old adit 250 ft. from the surface and has been making rich tuns-ina ever since. A holler and steam hoist have been installed and hand-jigs are treating the ore. Another fast developing tract is the Riesing ground, upon which four mills have recently been built. The latest addition is the Symmes lease with a 250-ton mill. Three concentrating tables, for saving the fine, have been added to the regular mill equipment. The greatest development of the mill work has been the resumption of the old adit and development work is being hastened. The W. E. Johnson land last week took third rank among the producers of the Joplin camp. Upon this land the Cleo Mining Co. opened a rich deposit of galena and zinc-blende at 97 ft., penetrating first a 5-ft. face of galena below which occurred an 18-ft. face of zinc-blende. Sufficient driving will be done to determine the extent of the deposit before the first shaft at the 100-ft. level is driven and the mill then will be erected. The Company has not been hindered by water.—The interest and attention of mining men during the last few weeks has been turned toward the Oronogo camp north of Webb City. The Granby Mining & Smelting Co., one of the largest concerns in the district, has been doing a large amount of prospecting and development work since the financial depression of last fall. The company has now added to the equipment of the mill a large addition and is developing another point of the mine. As soon as this work is completed the old adit will be reopened, and an extension of that field. Upon a 30-acre tract, north of the Oronogo Circle Mining Co.'s land, four drill-holes were sunk, finding ore from the grass roots to 240 ft. The cuttings are estimated to run from 4% in the upper levels to 23% in the rich lower levels. A shaft is now down and machinery installed. J. H. McGees and associates, of Carthage, have taken an option on the land and the old adit is now in the developing stage. Some of the most important work in the district is being done at present in the vicinity of Carthage, which is one of the latest important additions to the mining industry. The old Porter tract in the northwest part of the city is very active. This land has not been operated for some years until this past winter, when a new company leased the ground and began to drain it. A large pumping plant has been installed, and the old adit has been reopened when it broke down a few days ago. However, it will not be long until the ground is sufficiently free from water to enable the more shallow runs to be worked.—South of town a company of local men are developing a tract upon the Lamee ground. The shaft last week entered the main body of ore at 160 ft. At this point a 25-ft. face has been opened up. The dump pile is now rich in ore ready for treatment.—A good lead strike was made on the Weaver farm, northwest of the city, last week. The drill entered the ore at 127 ft. It is planned to have the shaft down to 175 ft. by the last of August. It is upon this farm that some of the richest strikes of the past year have been made.—On the J. H. Harris land, adjoining the Weaver farm, two levels have been developed at the 900-ft. level. Two drill-holes have been put down to an average depth of 240 ft. Ore has been found at the 100-ft. level and a lower run at
August 1, 1908.

MINING AND SCIENTIFIC PRESS

141

200 ft.—At Pierce City, east of Carthage, a rich strike was made recently which is the more important since the land around the city is virgin territory. A. B. Bowen & Sons made the strike on the Fred Smith farm. A large deposit of rich zinc-blende was struck at 65 ft., continuing to 95 ft. Five drill-holes have been put down, all showing the same formation. The extent of the deposit and its richness make it an important find.

Joplin, July 25.

NEVADA.

ESMERALDA COUNTY.

The controversy between the Goldfield Consolidated Mines Co., and the Jumbo Extension Mining Co. has been adjusted out of court. All future disputes between the Consolidated Mines Co. and the Jumbo Extension Mining Co. regarding orces or other questions are to be submitted to a board of arbitration, the rulings of which shall be final. The Gold Wedge claim goes to the Consolidated, subject to the leases of the Mohawk Ledge and the Mohawk Jumbo, both of which will hereafter pay royalties to the merger people. In return for the above, the Consolidated releases all claims for ore removed up to the time the action was instituted. The Consolidated Company takes the right to mine the Vinegarous claim, half the net proceeds to go to the Jumbo Extension, the title to the claim to remain as at present. Title to the Polervede claim remains with Jumbo Extension. Veins of the Polervede which may apx. in Consolidated ground may be mined by the Jumbo Ex. or Consolidated, with an allowance of $10,000 from the joint account to the corporation developing the vein, the ore returns to be divided half and half. This agreement will give an immediate and beneficial stimulus to affairs in the camp and a number of the lessees have already started work, on the same scale as when stopped by the injunction of the United States Court last February. The terms of the agreement between the Goldfield Consolidated Mines Co. and the Goldfield Combination Fraction Mining Co. were arranged on July 30, and the ratification will be made and announced on Friday, July 31. By the terms the Combination Fraction is entitled to all ore within the vertical boundaries of its claim, but grants to the Consolidated a contract to mill all its ores on certain fixed terms. It is stated that these terms are better than could be procured elsewhere, and at the same time will net the Consolidated a fair profit.

—The Baby Florence Co. has been completely re-organized and Lewis Rogers, of the Rogers Syndicate becomes general manager and is in complete charge of its affairs. J. F. McIlvie has been appointed superintendent under a new novel contract. He will receive one per cent of the net earnings of the lease give no guarantee. The Baby Florence is shipping from 15 to 20 tons per day running about $75. The lease runs until the second week in December. A new compressor has been installed and four power drills will be at work by the first of the week.—The Red Hills Mining & Leasing Co., which is operating a block of ground on the Red Hills property, added another shift to its working force and will now push development. The sluice shaft on the lease has reached a depth of 230 ft., and for the last 30 ft. a three-foot perpendicular vein has been followed. The mines of Goldfield produced during the week ending July 25 a total of 2452 tons, the estimated value of which is $315,175. During the same period the Tonopah mines produced 6965 tons of an estimated value of $156,175.

LYON COUNTY.

A company of California people, headed by A. L. Anderson, have taken a bond and lease on the Mountain View group of claims and an option on the controlling interest in the Red Crow Co.—The first shipment of ore was made from the Big 20 lease last week. The ore was hauled to Schurz and shipped to the sampling works at Hazen. Forty tons of the shipment will probably assay at least $100 per ton.

NYE COUNTY.

The apex-suit between the West End Co., Mining Co. and the McNamara Mining Co. has been amicably settled outside of court. The terms of the agreement are as follows: The right of the West End Co. to certain stock of the McNamara Mining Co. has been the subject of litigation in the courts is now recognized and confirmed by the latter. The litigation over the orebodies has been dismissed and the injunction against the McNamara Co. has been dissolved, and the West End Co. and its successors are released from all claims for damage on account of the injunction. Each company holds all veins, or parts of veins, found within the vertical boundaries of their respective properties, neither party being permitted to follow any vein, or parts of veins into the property of the other.—The Springdale mill, at Beatty, is rapidly nearing completion, and will begin operations during August. The plant is the property of the Springdale Mining & Milling Co., and may handle some custom ore in addition to company ore.—An explosion of a compressed-air pipe in the Belmont mine did some damage to the shaft and electric wiring, but no injury to any workmen.

WHITE PINE COUNTY.

James & Doran have started a force of eight men to work sinking a shaft on the Copper Bond No. 9. The property is a considerable distance southwest of the Veteran mine.—The Keystone churn drill, which Thomas Rockhill is sending to Snake valley for prospecting the placer fields between the valley and the Osceola Mtn., left Ely last week. The machine was hauled by teams and was released from all claims for damage on account of the injunction. Each company holds all veins, or parts of veins, found within the vertical boundaries of their respective properties, neither party being permitted to follow any vein, or parts of veins into the property of the other.—W. J. Corbett shipped two carloads of tailing from the old Monitor mill-dump to the smelter last week. The shipment amounting to 60 tons from which returns of $30 per ton are expected.—The Copper Mines Co., successor of the Ely Mines Co., is now doing some extensive development work on its property immediately north of the Star Pointer shaft of the Nevada Consolidated, where a force of 25 miners is employed.

OKLAHOMA.

OTTAWA COUNTY.

(Special Correspondence.—Miami, the infant of the mining district, is a busy scene. The large extent of the deposits and the unusually high percentage of ore in the dirt make this a camp of great interest. A number of prospects have been developed sufficiently to warrant a mill. Four plants are now operating and several in the course of erection. The Lucky Strike, which has been leased to the Kenwood Co., will build a mill of 160 tons in the near future. A new hill has been sunk. Three drill-holes on the 5-acre lease strike ore at 110 ft. with the face from 7 to 17 ft. thick.—A rich drill strike was made on the Baxter Royalton's land by J. W. Barnes. The dirt runs 20% zinc-blende. This is the third drill-hole showing ore on the land. The little Maxine, to the north of this lease, has made a strike with a 36-ft. face. This is the largest
WASHINGTON.

FERRY COUNTY.

(Special Correspondence.)—The lessees of the Republic mine shipped their second carload of ore to the Granby smelter, at Grand Forks, B. C., July 26.—The Advance Mining Co. has made a new strike on the 200-ft. level. It consists of several feet of highly mineralized quartz, with a 16-in. streak of high-grade galena. The company will double its force next month. O. F. Parmeter, of Covada, is the superintendent.—The Keller & Indiana Smelting & Development Co. has started work on the upper adit-level of the Grand, and will soon begin hauling ore to the smelter. A raise has been started to provide ventilation. A winze will be sunk on the main ore-shoot, to determine its direction. New track has been laid in the lower adit, which will be connected with the ore-shoot. A wagon road to the lower adit is under construction, and at the portal of that adit, ore bins will be constructed. The company expects to begin hauling ore about August 10 and will then install electric drills.

Republic, July 27.

OKANOGAN COUNTY.

(Special Correspondence.)—The Butcher Boy mine, at Chesaw, is shipping ore to the Granby smelter, at Grand Forks, B. C. The Grant and O lentangy quartz mines and the Bethel placers are the only active mines in the district at present, although several smaller properties are desultorily worked. A new government engineering staff is in the field checking past work for the establishment of the national boundary.—Operations have been suspended on the Palmer Mountain Tunnel & Power Co.'s property—both mine and mill. E. W. Biedler, the superintendent, has resigned, and rumor says that John Boyd, the general manager, has resigned also. F. G. Burnham, of Holyoke, Mass., who is familiar with the property, has arrived and will take charge of it for the present.—It is reported that Monroe Harman, manager of the Ruby mine, at the base of Mt. Chopaka, who has been East several weeks, is expected home in a few days, accompanied by a party of Holena, Mont., men, who will put up a chlorination plant for the treatment of the Ruby ore. There are several thousand tons of medium and low-grade ore on the dump and blocked out in the underestimation of the mine, which will not pay to ship, but may be profitably treated on the ground.

Chesaw, July 27.

STEVENS COUNTY.

(Special Correspondence.)—The First Thought Extension Mining Co. has been organized to operate the Effie R. group of three claims, lying east of the First Thought mine. The manager is G. T. Evans, of Orient, Ferry county.—The Hester Mining Co. will resume work on the Regsna mine, on Pierre creek. —A three-year contract has been made to furnish 75 tons of iron ore per month from the Valley mine, at Valley, to a Spokane firm, for the manufacture of mineral paint.—Considerable native silver ore has been found on the 100-ft. level of the Ark Group Mining Co.'s Silver Queen claim.—Two more furnaces have been blown in at the Northport smelter to accommodate smelting ore from the Josie mine, of Roseland, B. C., and the First Thought mine, near Orient.—The mines from two to ten miles down the Pen d'Oriille river from Newport, are improving, and several will be operated this year that have been long time idle. The promised activity arises from the announcement that the Idaho & Washington Ry. will be continued down the river.—The Borntite Mining & Smelting Co. has purchased the Lucky Bill and Ballarat mines, near Northport, and now owns a group of ten claims.—A contract has been let for a 100-ft. adit on the Liberty copper mine, near Newport, and several furnaces have been blown in the 385-ft. level, face was uncovered. A shaft is being sunk and preparations are under way for the erection of a mill.—The Emma Gordon, the new 400-ton mill, has been making a record since its initial run. The tonnage from this new plant has run as high as 200 tons of clean concentrate per week.

Miami, July 25.

MINING AND SCIENTIFIC PRESS

August 1, 1908.

[The text continues with mining news and company updates.]
Special Correspondence.

LONDON.

The first annual report of the Tonalin (Mexican) Mining Co., Ltd., which has just been issued, is rendered interesting by the conflict of opinions between the general manager and the mining engineer as to the extent of the ore reserves and the metal-content of the ore. The general manager is Paddy Gosset, who was promoter and vendor, and the engineer is G. W. Schneider, who views the property as a stranger. Mr. Schneider estimates the ore reserves at 5,750 tons, averaging about $69 per ton, and the dump at 20,000 tons averaging $20. He is also careful to apply to the ore reserves the objective ‘probable.’ Mr. Gosset, on the other hand, puts the dump at 30,000 tons, running $50 per ton, and the probable ore reserves at 12,000 tons, and protests against Mr. Schneider knocking out the high assays in calculating his averages. Mr. Gosset, in his report, in an affable manner excuses Mr. Schneider as “he has had the disadvantage of not being acquainted with our customs, and could not be expected to completely grasp the situation.” Naturally Mr. Gosset is prejudiced, but I believe that two unprejudiced engineers would be just as liable to differ in their estimates. The ore is silver sulphide, containing some gold, and occurs together with white quartz inandesite. The width and contents of the veins vary widely. As regards the method of treatment, it is fairly certain that the Butters cyanide process, so successful in the Uda mine in Canada, will be adopted. The cash resources of the company are not great, and most of the expenditure is going into development at present, in the hope that if large bodies of ore should be opened up it will be easier to raise the necessary funds for a mill.

There is every prospect of the De Lamar mine, Owyhee county, Idaho, again earning profits for its English shareholders, for during the last two years sufficient profit has been made to wipe out the losses of three years ago. This mine was originally floated in London, in 1891, by Mr. Bratnober, and for five years considerable profits were made. Later on, however, the main veins gave out, and the profits shrank. In 1901 the company was reconstructed and the nominal capital increased from £500,000 to £1,000,000. During the ten years of its life the old company distributed £500,000 as dividends. For the first five years the dividends averaged 22½%, but sunk afterward to 2½%. With the reconstruction the reduced capital made the rate of dividend appear higher again, and during the four years 1901-5 a total distribution of £70,000 represented 57½% of the capital. During the next year losses to the extent of £16,000 were incurred, which have since been wiped out by the profits during the two years ended March 31, 1908. The mine has some extensive ore reserves, and with the excellent modern plant now installed should continue to yield profits for some years to come.

During the year ended March 31, 1905, the quantity of ore treated was 32,602 dry tons, assaying $7.74 gold and $3.78 silver. The yield was 15,719 fine oz. gold and 155,994 oz. silver, the extraction being 92% and 95% respectively. The tendency has been to finer grinding, and practically an all-slime process has now been adopted.

The appearance of the prospectus of the Lena Goldfields, Ltd., is some indication that the financial side of mining is taking a turn for the better in the city of London. This company has been on the stocks for quite a while awaiting the convenience of financial houses and investors generally.

It has been formed by the Russian Mining Corporation, a company supported by the Venture Corporation, the Consolidated Mines Selection Co., the Consolidated Goldfields of South Africa, and certain continental financial houses. Its function is to acquire the whole or the larger part of the share capital of the Russian company of similar name which has operated the properties for forty years. The properties are very extensive, consisting of four separate groups, totalling over 100 square miles. They are situated in the extreme northeast of Siberia. The output from 1863 to October, 1906, was 2,392,021 oz., and during the year ended October, 1907, the output was sold for $434,000. The deposits are ancient river-beds and are worth nine dollars per cubic yard. They are worked as drift mines, the development and extraction of gravel proceeding throughout the whole year. The average output is over 1,000,000 tons per year.

A few months ago, when referring to the Le Roi No. 2 at Rossland, B. C., I mentioned that it was the intention of the company to take up the Vancouver group of silver-lead claims at Slocan, if the development work turned out well. Alexander Hill has just returned from a visit, during which he found the mine turning out so well that he has recommended the purchase of the property. The company has accordingly been named the Van Roi Mining Co. The capital is $34,500, divided into 30,000 preference shares of $1 each, and 90,000 deferred shares of one shilling each. The preference shares are now being offered for subscription, and the proceeds will provide the purchase price, $100,000, and the necessary working capital. Subscribers to preferred shares will be offered one deferred share for each preferred share allotted, and the other 90,000 deferred shares go to the Le Roi No. 2 Co. In satisfaction for the money spent in development work the preferred shares are entitled to 40% dividend each year, and any further profits will be divided into four parts, one part going to the preferred shares and three parts to the deferred shares. When $30,000 has been distributed on the preferred shares, the preferred and the deferred will rank equally for dividend. The ore deposits are of lenticular shape and are said to be difficult to sample accurately. Mr. Hill, however, estimates that 60,000 tons are ready for extraction, averaging 4½% lead, 10% zinc, and 15 oz. silver. There will be no great trouble in concentrating, and he estimates that the production would be 4,900 tons of lead concentrate, averaging 40% lead, 11% zinc, and 35 oz. silver, and 575 tons of zinc concentrate averaging 45% zinc, 2% lead, and 40 oz. silver. The net income from these is figured at $50,750 for the zinc concentrate, and $292,157 for the lead concentrate. The costs are taken at $2.65 per ton of ore, equal to $161,650, leaving a profit of $211,287, or $43,000.

KALGOORLIE, WESTERN AUSTRALIA.

Koolyonoobyn District.—Trans-Australian Railroad Surveys.—Gold Production for May.—Ivanhoe Report.—Decision in Gold-Stealing Case.—Kalgoorlie School of Mines.

Developments at the new find in the Koolyonoobyn ranges are not so promising as they appeared at first. The State Mining Engineer is to report. The survey party, consisting of 30 men and 90 camels, for the trans-Australian railroad left here last week. They will keep on about the 31st parallel and be out nearly a year. A number of prospectors will follow. A well-equipped prospecting party left Southern Cross on June 1 and will cut across to Mt. Magnet. The Minister for Mines has given six-months’ supplies. Splendid rains have fallen, so parties in the field ought to have little trouble. The gold output from the State in May was valued at $2,100,000, and dividends totalled $65,000. Kalgoorlie’s May production was $1,600,000 from 130,000 tons. Affairs at the Associated, Great Boulder, Horseshoe, Ivanhoe, and Kalgurli are very satisfactory, but the Brownhill, Associated Northern, and Oraya group on the Eastern side of the belt are anything but promising.
The returns and dividends for May are as follows:

- Loss.

Connection has been made between the Main and Edward's shafts at a depth of 2200 ft. in the Great Boulder, the ore being high-grade. The latter shaft is to be the main hauling shaft, and Thompson & Co., of Costamania, Victoria, are making the new hoist. It is to be a vertical, twin-tandem compound, direct-coupled, condensing engine, with two high-pressure cylinders, each 16 in. diam., two low-pressure cylinders, each 28 in. diam., and a stroke of 42 in., steam pressure to be 160 lb. per square inch. The drums are 12 ft. diam., and the engine is capable of lifting 3 ton. The hoist will reach 4000 ft. The Golden Horseshoe has just started its 69-drift Ingersoll-Rand air-compressor, and also a 500-kw. generator, driven by a steam turbine, made by the A. E. G. The Kalgurli has started sluicing away its filter-press residue. This company has an advantage over others in this line, as it is 140 ft. above the surrounding country, and consequently no pumping is required.

The Ivanhoe annual report makes interesting reading. It is not a long one, but everything is there, while the mine-plans are very creditable. Ore reserves estimated by the general manager, Mr. Nicholson, total 956,737 tons, at $12.52 per ton; while the estimates of the consulting engineers, Bewicke, Morecroft & Co., are 1,049,714 tons at $11.56 per ton. In a mine so well opened up as the Ivanhoe, one would think that the creditable estimate given above would be below the truth. This mine has paid $3,500,000 in dividends to date. Costs for the past year totalled $3,523 per ton. The tonnage in 1907 was 231,500 for gold, valued at $2,500,000, and the profit was $1,200,000, of which $1,200,000 was paid in dividends. Development for the year totalled 6964 ft. It was feared last month that there would be trouble with the engines on hoists and stationary engines, as they wished for higher wages. The case was cited for the Arbitration Court, but at a conference with the Chamber of Mines, a 12-months' agreement was arrived at as follows: $1.30 for underground hoists and the minimum for surface hoists; $3.36 minimum for surface hoists; and $3.60 for main shaft hoists per 5 hours, the week to total 47 hours. Although there have been no reported cases of gold-stealing in the mine, it is feared that the practice will spread, and all miners are on the lookout for any sign of it. A case was tried some time ago in which a man was seen by the detectives to take a parcel of telluride specimens out of a cart and place it in a tank. He was arrested and given three months' hard labor, but appealed to the Full Court in Perth. The Judge decided that when the police catch a man he must have the gold actually on his person, and the conviction failed. The Judge remonstrated at the same time that as long as the law stood it was very difficult to secure convictions. However, the police have re-arrested the accused on another charge. It is just on these apparently trifling technical points that most of the offenders get off scot free.

There are 284 students attending the local School of Mines. Technical education in this State is under Government supervision, and besides the local school, colleges are in full swing in Boulder City. Menzies, Coolgardie, Cue, and Perth, all under the control of F. B. Allen, Director of Technical Education for W. A. The local School of Mines is well equipped for teaching assaying, chemistry, electricity, and engineering. A very fine geological museum is in the same grounds. Besides containing maps, plans, photographs, and specimens of ore from this State, it also contains specimens from all parts of the world, being valuable to the students. The public are also admitted. R. B. Nicholson, of the Ivanhoe, is to visit England shortly. Mr. Borrows has resigned the management of the Perseverance, and proceeds to Mexico by way of London. Temporarily Hogan Taylor is in charge of the Perseverance.

**TORONTO, CANADA.**

*Increased Output From Cobalt.—Exploring Under the Cobalt Lake.—Government Explorations for Coal in the East.—Iron-Ore Deposit Near Montreal.*

The shipping mines of the Cobalt camp now number 26, the output of which for the first six months of the year was 9251 tons, as compared with 6549 tons for the corresponding period of 1907. In addition to the increased volume of the output, the value per ton is higher, owing to the extensive treatment of low-grade ores at the concentrators before shipment. The La Rose, O'Brien, and Nipissing are well in the lead as to tonnage and assay-values. The month of July opened well, shipments for the week ending July 11 being 433 tons, from the following mines: Cobalt Lake, 47; Kevi Lake, 50; La Rose, 41; Nipissing, 63; Nasey Lake, 28; Allen, 29; Peterson Lake, 20; and Silver Queen, 90 tons.

Another rich discovery has been made at the Nipissing on new territory lying north of Cobalt town, opened up this season. From two to three miles of trenching has been done on this lot leading to the discovery of several good veins, and this week a calcite-silver vein was encountered at a depth of 125 ft., having 4 ton. of ore containing several thousand ounces of silver per ton. At the Chambers-Ferland development is being actively pushed under the direction of W. H. Jeffrey, an experienced mining man. Three shafts are being sunk. Shaft No. 1 is on the vein No. 4, between the La Rose and Nipissing properties, and will be cross-cut at the 100-ft. level to strike parallel veins. Shaft No. 2 is down 90 ft. on the rich O'Brien vein, and is being worked and cross-cut. Shaft No. 3 is on vein No. 7, close to the La Rose. If juxtaposition counts for anything, this property should hold a leading place among the shippers. The Little Nipissing Co., while not successful in striking anything valuable on its own ground, where development is being steadily continued, is doing very well with the Peterson Lake, which is being worked on by lease holders. A new shaft on the other property has been started to pick up the vein which left the shaft at 80 ft. The Cobalt Lake Co. has issued a statement showing the work done during the first six months of the year, which included 1222 ft. of driving, 160 ft. of sinking, and 30 ft. of raising. Sinking has been discontinued for the present, and the force is driving adits beneath the Lake at three points. The Silver Leaf realized upward of $259,000 on the last two tons of ore shipped. The new shaft has reached a depth of 170 ft., at which point the vein, originally struck at 125 ft., shows a width of 4 in., and assays about 500 oz. silver per ton. At the 125-ft. level a station has been cut, and driving along the main vein will be started. A fire at the power house of the Silver Queen on July 15 damaged the plant to the extent of about $25,000. In the course of cross-cutting at the Crown Reserve on the 50-ft. level of No. 1 shaft, a vein 19 in. wide was struck, running parallel to the main vein about 5 ft. distant. It shows a high silver content. Some good finds in the unsurveyed territory south of Lorraine township are reported. Bert Grover has obtained two large nuggets of nearly solid silver from his location. At the Keeley property good ore is being taken out. On the Cragg location, in Smythe township, on the Montreal river, a vein 3 in. wide has been encountered in the diabase, heavily impregnated with native
MEXICO.

Comment on New Mining-Law Project. — Oaxaca Smelting Plants.— Blowing in of Chihuahua Smelter. — Greene-Canaan Copper Company.

The provisions against foreigners and foreign companies acquiring mining lands in Mexico, that are embodied in the proposed new mining laws continue to be widely discussed throughout the Republic, both by the people and by the Mexican press, native and foreign, and there is an evident belief on all sides that the provisions were actuated by an anti-foreign feeling. This has led to a rather bitter article in one of the leading dailies of Mexico City, La Patria, edited by Lic. Emeterio de la Garza, Jr., a prominent young attorney. The article touches lightly on some of the provisions limiting the rights of foreigners, and then states that the proposed laws are not based on any anti-foreign feeling, but represent a movement in the direction of sole practised by foreign corporations for the handling of the large bodies of low-grade ore. At the beginning of this century Guanajuato was a presumably worked-out and practically abandoned camp, with scarcely a foreigner in it. Then the Sirena was taken up by foreigners (the Guanajuato Con. M. & M. Co., of New York), and it was followed by others, all of whom have invested fortunes in development work, and in the erection of immense reduction works until, from almost nothing ten years ago, it stands today in the front rank of the gold and silver-producing districts of the world. There is scarcely a property in Guanajuato which is not a repetition of the story—worked by the Mexicans while in banana and until the water was reached, then abandoned until taken over and opened on a large scale by foreign capital. Furthermore, this capital has been almost wholly American. Others did not see far enough ahead; and in fact, many large British holdings were sold to Americans.

The Oaxaca smelter, of the Oaxaca Smelter & Refining Co., was sold at public auction on the first of July, and was bought by the bondholders by H. D. Wilde, former auditor of the company, at $275,516, about two-thirds the cost of construction, no other bidders being present. Another representative of the bondholders, H. M. Holbrook, has gone to New York to consult with his principal, and it is stated there is a likelihood of the plant being started in the near future; at least before the first of the year. The other Oaxaca smelter, known as the Magdalena, of L. R. Hauer, which was blown in to smelt and clean up all the old stock of ore and stuff on hand, and convert them into funds, is now down again—it is feared indefinitely. But there is a confidence in the permanency of two other plants blown in during the week ending July 18. One is the new plant of the American Smelting & Refining Co., situated just outside of the city of Chihuahua, which was blown in on the date mentioned. Only one furnace was put in blast, but others will be added as things get into working order, the effect of which will be most encouraging throughout the State, but more particularly to the city of Chihuahua and the region.

There are three of the immense new furnaces of the Greene-Canaan group which have not been put into blast (Law), as the company cannot be over-estimated. It removes a cloud that has been over the entire State of Sonora, and creates a feeling of relief in Mexico. It is stated that with the adoption of the caving system at the mines, with its 3000-ton concentrator, the use of fuel-oil where possible, and other improvements and changes instituted by L. D. Ricketts, the general manager, the Greene-Canaan Copper Co. will from this time forth produce copper at $6. per lb. or less.

JUNEAU, ALASKA.

Coal Land Regulations.—Copper River Development. — Bering River Coalfield.

Local politicians and mine-operators are discussing the effect of recent legislation on the development of coal in Juneau, Alaska. By an act of Congress passed last year, it was provided that consolidation of claims is limited to 2500 acres, or 15 claims of coal-land. Any one having an interest in one of these maximum consolidations cannot acquire any more coal-land in Alaska without forfeiture, of rights in both. This provision is intended to prevent the hoarder of stock in one large corporation from holding stock in another. Any combination in restraint of trade, either by way of ownership, operation, or selling of coal, is made illegal under pain of forfeiture of all rights to the Government. The law is made applicable both to individuals and to corporations, but infractions will be difficult to punish. Locally it is believed that the idea was to prevent the Morgan-Guggenheim interests from gobbling up too much of the coal resources of Alaska, but the immediate effect may be to discourage the investment of capital in any comprehensive scheme, such as seems to be necessary to make coal mining a financial success.

The development of the Copper River country is dependent upon the construction of the railroad from the coast. Rivalry between two competing railroad companies appears to have been ended for the present, and the Alaska Northern undertaking is no longer under way in the railroad from Cordova to Abercrombie Rapids, whence a steamboat on the Copper river will connect with a landing on the Chitina river, the distributing point for the Copper river district and 160 miles from the coast. This scheme is backed by J. P. Morgan and M. Guggenheim's Sons. Of the Copper River & Northwestern railroad 27 miles have been built from Cor-
MINING

the Important Features of
the present mining operations at
the Bonanza mines. The owners of the mines participate in the railroad
business. By a contract made with Harry Havemeyer, Norman
H. Shults, and James H. Ralph, it is stipulated that the
Morgan-Guggenheim syndicate shall accept ore offered for
delivery at the landing of the Chittina in 1899, and pay for it,
with freight charges. The shipment, according to terms
already specified. Thus the mine-owners are in a
most comfortable position. Stephen Birch is superintendent.
The ore is rich. There is said to be, already opened
up, not less than $2,000,000 worth of 25% ore, estimating copper at 11c.
per lb. The limestone-greenstone contact,
in which these deposits occur, runs for several hundred
miles, and two other promising mines have lately been dis-
covered. Cordova, the terminal of the railroad, is three
miles from the old cannery at Orca. From Cordova it is
110 miles to the Bering river confluent, or 90 miles from
the place where the railroad crosses the Copper river. M. K.
Rogers planned to construct a breakwater at Katalia, but
he abandoned the scheme on account of its cost. His con-
deection with the Guggenheims was in 1900, and he has
devoted the first three years of work to the Bering river (26
miles) to Controller Bay, to a port on Kanak island. The
U.S. Navy Department has tested the coal and found it to
be as good for steaming purposes as the Pocohontas. It is
much to be hoped that there will be no farther delay in
the systematic development of the coal and copper mines,
for they will become the basis of profitable industry long
after the rich gold gravels are exhausted, and will serve as
points of departure in prospecting for gold-quarts veins.

Butte, Montana.

Parrot Copper & Silver Mining Co.—Reins Copper Co. Annual
Meeting.—Development of East Butte Copper Mining Co.—Re-
sumpion of Work at Other Mines.

The Parrot Copper & Silver Mining Co., one of the Amal-
gamated subsidiary companies, has its greatest prospects
in its new mine, the Little Mina, which, under the direction
of H. A. Galloway, is being developed into an important
producer. The future of the Parrot mine itself is a problem,
but the Little Mina is no longer so. It is opened by a shaft
1,000 ft. deep, with three levels, at depths of 600, 800, and
1,000 ft. respectively, and preparations are being made to
sink the shaft deeper. At present mining is con-

Prizes for Collection of Ontario Minerals.

A prize of $100 cash is offered by J. B. Tyrrell, mining
engineer, of Toronto, for the best collection of minerals
collected in the Province of Ontario during the year 1908
by any one not employed as a collector by a public institu-
tion or by dealer in minerals. The collection must contain
at least 50 mineral specimens, and it is suggested that where
convenient the size of the specimens should be 2 by 6 in.
Each specimen must be 130 ft. long and 2 ft. wide; from
which it was obtained, and the date on which it was
collected. No specimen will be considered unless so labeled.
A typed list of the specimens, with names of minerals
and localities, in triplicate, together with a declaration
stating that they were personally collected by the signer in
the Province of Ontario in 1908 at the localities stated,
with the post-office address of the collector, must accompany
each collection. The collections must be addressed: Ex-
aminers, Tyrrell Prize, Government Assay Office, Bellville,
Ont., and must be sent prepaid, on or before December 1,
1908. They will be opened and examined jointly by Prof.
Wm. Nicol, of the School of Mining, Kingston, and Prof.
T. L. Walker, of Toronto University.

If requested the collections will be returned, charges col-
lect, as soon as possible after the prize is awarded.
Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Imported pebbles for use in tube-mills have finally been discarded by a number of Rand mines, and the pebbles falling out of the "banket" ore on crushing, are used instead.

A level line is a curved line, the tangent to which is always perpendicular to a plumb line. A horizontal line is the tangent to the level line, at the point under consideration.

Wrought-iron riveted to cast-iron is liable to excessive corrosion through the formation of a galvanic couple. This action was proved to be one cause of the failure of the Tay bridge.

A wye-level, badly out of adjustment, will give absolutely correct results if the sum of the length of the back-sights, of any one circuit, be made exactly equal to the sum of the fore-sights.

The term 'Artesian' is now used by the U. S. Geological Survey to designate the hydrostatic principle by which confined waters tend to rise by virtue of the pressure-head due to the height of the water-column, irrespective of whether this pressure be sufficient to lift the water to the surface and produce a flow or not.

Liquid air has not been a success for developing power. The liquefaction of air to produce one gallon of the fluid requires an expenditure of energy equivalent to 28 hp., the average cost per gallon being about $1.76. Only about 2/3% of the energy expended in producing the liquid air can be recovered when it is applied as a motive power in an engine.

Scale-forming materials may often be eliminated by the use of feed-water heaters. This is due to the fact that waters containing much calcium and magnesium carbonates when heated to the usual temperature in feed-water heaters (200-210° F.), gives up the excess of carbon dioxide that holds the calcium and magnesium carbonates in solution, and the latter are precipitated and removed before the water enters the boiler.

Brick walls may be rendered impervious to water by applying alternate washes of the soap and alum solutions. The proportions are 1/4 lb. castile soap to one gallon of water, and 1/2 lb. alum to four gallons of water. The soap wash should be applied boiling hot and allowed to stand 24 hours before the alum wash is put on. Two to three alternate washes of each solution will probably be required. This is known as Sylvester's process.

Pintsch gas is made from high-grade petroleum distillate and is a fixed gas, which, when compressed, has an illuminating power six times as high as coal gas. Illuminating gas of ordinary composition upon being compressed precipitates the heavier hydrocarbons in the form of liquid or tarry products, materially reducing the incandescent effect of the gas.

The peculiarity of Pintsch gas is its remaining fixed under a compression as high as ten atmospheres.

Sodium amalgam must be made with great care in a cast-iron retort, or in a mercury flask, adding the metallic sodium gradually in small pieces. The quicksilver must be perfectly free from moisture, else the sodium will be oxidized in decomposing the water, and will thus be rendered unavailable for amalgamating with the quicksilver. This will show why it would serve no useful purpose to add metallic sodium in the mortar in stamp-milling. The sodium would be converted into caustic soda (NaOH) at once on coming in contact with the water.

The water-gas system consists in the decomposition of steam at a high temperature by incandescent carbon, thereby producing hydrogen and carbon dioxide. In the presence of incandescent carbon, the carbon dioxide is reduced by taking up another atom of carbon, forming carbon monoxide. In practical working the reduction of the carbon dioxide to monoxide is never quite perfect, the unpurified gas usually containing about 3% of carbon dioxide, which may be largely eliminated by some system of purification. The gas, in the process of manufacture, passes from the generator to the carburetters, where it is enriched by means of crude oil or cheaper distillates; hence the name 'carburetted' water-gas.

Direct observations on the sun, for the determination of true meridian, have almost entirely replaced the method involving the use of solar attachments. Among the numerous advantages offered by the direct method are these: The field-work may be done without reference to a previously calculated position of the sun, and the reductions made at any convenient subsequent time, the time-observations being the only datum needed in addition to the instrumental readings. The solar attachment, besides being an expensive instrument, is a delicate piece of apparatus and easily gets out of adjustment. It is also difficult and tedious to adjust. The direct method may be used on partially cloudy days on which the early form of the solar attachment (the Burt) is entirely unavailable. The use of the solar attachment involves previous calculation and more separate settings of verniers, and hence introduces more chance of errors in manipulation. There is no doubt that the direct method gives more accurate results for an equal amount of care in the manipulation. On the other hand, the direct method is not so advantageous in places when it is desired to trace a meridian directly on the ground. The manufacturers claim that solar attachments may be used as auxiliary telescopcs for sighting down steep shafts, but their usefulness for such a purpose is questionable, since they are commonly made with low magnifying power. It may be noted here that the following formula is best adapted for reducing direct observations, in that it allows all the computations to be made by one logarithmic operation:

\[
\cos \frac{1}{2} Z = \sqrt{\frac{\sin \frac{1}{2} S \times \sin (\frac{1}{2} S - \text{Pole-dist.})}{\sin \text{Co-alt.} \times \sin \text{Co-lat.}}}
\]

where \( S = \text{Pole-dist.} + \text{Co-alt.} + \text{Co-lat.} \).
Discussion.

Readers of the Mining and Scientific Press are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

Mining Stock as Bank-Collateral.

The Editor:

Sir—Two articles have appeared lately in the Mining and Scientific Press that have interested me greatly. The first was the communication from M. L. Requa, regarding the use of mining shares as bank-collateral. The second was T. A. Rickard's presentation of figures supplied by F. W. Bradley on the cost and production-record of the Bunker Hill & Sullivan mine. While these articles were not intentionally written with reference to the same subject, to my mind they both suggest, with almost equal weight, the value of properly presented mine-reports in the legitimate conduct of the mining business.

Mr. Requa's communication also takes the point of view of an outsider in showing what is desirable to have in the way of information that will make mining stocks as useful as other properties of the same value, while Mr. Bowler's figures are a concrete illustration of what may be done to clarify the haze that usually surrounds the affairs of a mining company. To a certain extent, Mr. Requa's statements regarding the inavailability of mining securities as bank-collateral, require some explanation. The banker does not invest money, he loans it. What is imperatively required of a bank-collateral is a ready market. Next to that, of course, is its intrinsic value. I happen to know that in New York certain mining stocks like the Amalgamated are freely taken by the banks as security in spite of much widespread and bitter criticism of the methods of that corporation, and of the intrinsic value of the stock in proportion to the stock-issue. The reason for this is that dealings in Amalgamated stock are in large quantities, and there is seldom or never any difficulty in disposing of considerable amounts of it at the quoted value. I have heard it said that Standard Oil stock, of which the earnings are far superior to those of the Amalgamated, is considered far less desirable as collateral, the reason being that Standard Oil stock is dealt in only on the 'curb,' and usually in small quantities. Of course, the shares of a mining company, the value of which are properly verified, are just as good security as real estate, but if the shares are not widely known, and not marketable, they must be treated exactly as real estate; that is, they would be good security for a mortgage, but not for a demand-loan.

I believe investigation would prove that this state of affairs exists all over the world. South African gold-mine shares of good repute are considered gilt-edged securities in the London market, and those of many other mining companies, in all probability, also are. In this country, the shares of most large mining corporations are available if they are traded in on the New York or Boston exchanges or curb markets, in spite of the fact that many of the most prominent of these issues have shown wide varia-

tions in price. It seems probable that the average man who refers to the mining business has his eyes set on a certain portion of it. People in the Rocky Mountain region when they speak of mining are apt to refer only to precious-metal mining, meaning by that, mines engaged in the production of gold and silver. I, have known people who actually had to stop and think before they were sure that the Standard Oil Co., the United States Steel Corporation, and the Colorado Fuel & Iron Co. are all mining companies. A vast number of people are interested in the shares of enterprises which have issued from one to five million shares of stock, representing investments either wholly fictitious or ridiculously small in comparison with the capitalization. This is a type of financing extremely common in the West. I venture to say that such corporations may be numbered by the thousand. A large number of people in thinking of mining stocks have in mind this kind of stocks, and sub-consciously place the real mine-stocks in such a different category that they assume them to belong to another business altogether. This kind of financing is essentially of the 'wild-cat' order. The lightning strikes one of them once in a while, and makes the capitalization good, but on an average, they are quite worthless from the banker's point of view.

Such securities are dealt in on a number of local exchanges in the West, such as those of Colorado Springs, Salt Lake, Goldfield, and San Francisco. These exchanges publish quotations, but the quotations are very often as empty as the properties they represent. You can sell a few hundred shares of a Wild-cat for a few dollars almost any time, but when it comes to realizing a considerable amount of money from such securities, the man who has the stock for sale is apt to find that the price can be very easily depressed. Bankers and investors have discovered long ago that there are only two ways of establishing the value of the average mining-security. They must either make a private examination, or depend on the extent to which such securities are backed by financiers and by the public. In the ease of the Amalgamated, and of a great many other companies, the securities are given a certain importance and strength by the names of the men who are publicly known to be interested in them. The actual value is not easily verified. The public is satisfied to guess at a value, or it takes it for granted. The above is, I believe, a fair representative of the state of mining-securities in the United States.

But since to every rule there are some glaring exceptions, we find that there are instances of mining companies which place before the public such information that any intelligent man may form as good an idea of their value as he can of the value of any other form of property. As examples of this, I may cite the reports of the Tennessee Copper Co., the Utah Consolidated Copper Co., and the Bunker Hill & Sullivan. These reports contain substantially the following information: first, the ore reserves developed in the mine; second, the record of ore mined for the year, and the output of metals realized; third, statements of construction-work com-
pleted, under way, or contemplated; fourth, costs of current operation of mines, mills, and smelters for the year; fifth, a balance-sheet showing the capital expenditures for various purposes to date.

Such reports vary considerably in their individual 'make-up,' but they all contain the above information. The reports of the Alaska-Treadwell and lately of the Bunker Hill & Sullivan, have gone farther. They show a complete record of the ore-production in considerable detail, for a period of years, or from the beginning of the enterprise to date, together with the operating-costs for the entire period. This information is exceedingly valuable and instructive, because it shows at a glance not only what the record of a property is, but what its tendencies are, that is, whether it has passed its zenith and is diminishing in prosperity, whether the costs are increasing or diminishing, and in general throws some light on the future as well as on the past.

The reports issued by John Taylor & Sons of London on their various properties also have this excellent feature, but they also contain what has been pointed out by T. A. Rickard as a vicious feature, namely, the procuring of money for construction and improvements not out of the profits but out of fresh shares issued by the company, and often sold at a high premium. I have attempted to point out in other communications that such expenses are really in the long run true operating-costs, and ought not to be charged to capital account, at least not altogether. The result of this system is that in the reports of John Taylor & Sons with regard to the Mysore mine, for instance, we find that certain important sums have been paid as dividends that really came out of the stockholders' pockets. But setting these considerations aside, a beauty of the reports is that they disclose these important facts, and the stockholder is furnished with information by which he can use his own common sense to put a price on his property.

What I believe to be the best statement of any with regard to the affairs of a mining company, is the one recently gotten out by Mr. Bradley and published in the Mining and Scientific Press of July 4. This statement is a presentation of a circular sent by Mr. Bradley to the stockholders of the Bunker Hill & Sullivan Mining & Concentrating Co., giving the following information: first, the present condition of developments in the mine with an explanation of how the ore-estimates are arrived at; second, a complete record of the output of the mine from the beginning, showing the recovery made, and the prices received for metals during various periods; third, it shows the cost of mining, of concentrating, and of plant for various periods and for the whole period; fourth, it gives the various conditions under which the ore was marketed, and the cost of marketing to the mining company by periods from the beginning of operations and for the whole period; fifth, it gives the future expectations of the mine, based upon experience to date, in the way of costs, prices, grade of ore, and ore available.

Such a statement is what stockholders want, and what they need. It shows with absolute clearness what may be expected of the property. If a property be honestly run for the money that can be made out of it for the stockholders, there can be no objection to issuing such statements, except that in enlightening the stockholders, rivals may be enlightened also. In the majority of cases reasons for secrecy are far-fetched, and are much more likely to cloak intentions on the part of the management to conceal records or transactions that they are ashamed of. It is among the objects of the Mining & Metallurgical Society of America to discuss such questions as it can to advantage with reference to matters of public policy connected with the mining business; and among the questions that have been thought of for consideration is this very one of what a mining company should report to its stockholders. I am glad that the engineers who have been foremost in issuing complete and satisfactory annual reports, like Messrs. Bradley, Channing, and Requa, are in the Society, and it is to be hoped that some day the Society will be able to recommend to the public a method of issuing annual reports by mining companies that will be generally heeded and that will have a beneficial effect.

Diffusion as a Factor in Ore Deposition.

The Editor:

Sir—The paper entitled 'Diffusion as a Factor in Ore Deposition' by Lewis T. Wright, in your issue of June 20, is of unusual interest as an expression of a kind of criticism of which many current theories of ore deposits stand in need. In so far, however, as the author attempts to disprove the effect of Soret's principle in segregating the metallic content of molten solutions, I believe him to be in error in assuming a parallel between a process which may be observed in a slag-pot, and a process such as is conceivable in nature. The fundamental difference lies in the time-element. In the case of the copper-slag, no sooner has a differentiation taken place than solidification of the magma ensues, whereas in a process of nature this need not necessarily be the case. Let us consider the sequence of events in the instance of a molten magma at rest and in contact with solid rock. In the event that the aqueous content of the magma be sufficient it is generally conceded that the basic minerals will crystallize out first, followed by the less basic, and last of all the free silica. Under these circumstances, as Mr. Wright states, a concentration will take place according to Soret's principle, of which the maximum is a function of the temperature-ratio, and, should rapid cooling follow, the differentiation of the rock would be too slight to result in an oroby. If, however, the cooling be so gradual that the basic minerals alone crystallize at the contact, while the solute remains fluid, the equilibrium of the latter will be disturbed, and further concentration will occur with repeated crystallization at the contact. Thus can the effect of Soret's principle become cumulative and account, together with other factors which it is not pertinent to specify, for the formation of an oroby.
at the periphery, but, according to the theory of their genesis, such deposits must be sought in coarsely crystalline rocks rather than in eruptive glasses or their artificial counterparts. The application of J. H. Vogt's theories may be open to controversy, but not the principles on which they are founded.

H. H. Knox.

Cornish Pumps.

The Editor:

Sir—As my experience with Cornish pumps of late has been confined almost exclusively to an occasional glimpse of one at some abandoned mine, I am hardly in a position to discuss their relative merits or defects, but when I read such sweeping denunciation of all forms of departure from the beam-engine type as appeared in your issue of July 11, I feel that a few words might be said in justification of those who have chosen more modern appliances. I shall make no attempt to disprove the reliability of the type of pump now operating at Linares, as my figures would seem small in comparison to the years of service performed there. If a proven reward of years were all that is required of pumps, we would need no further reference as to the best type, but unfortunately the factors of first cost, adaptability to existing conditions, and efficiency, have to enter in. The factor of first cost is against all forms of Cornish pumps, as is also their adaptability. The best results from these pumps are obtained in pumping from a perpendicular shaft where there is a permanent pumping level. As to handling a sudden increase of water, there is no pump which has such a positive limit to its capacity. As I know of no record equaling that made in Spain, it seems to me that there is no better way of justifying modern practice, than the simple statement of the possibilities and limitations of the different types of plant now in use.

With the beam-engine Cornish pump, the steam acts directly on the pump-rod. In order to make use of the expansive power of the steam, it must be cut off as early in the stroke as possible. To accomplish this, as high a steam-pressure as the pump-rod will stand is applied at the beginning of the stroke, and is cut off at about one-third the length of the stroke. The weight of the rod, and the expansion of the steam, carry the stroke to the end, when it stops suddenly. If the speed of the pump has to be increased, it cannot be done by increasing the steam-pressure without endangering the pump-rod, so it has to be done by retarding the steam cut-off. This allows of less expansion, and greatly reduces the efficiency of the pump. If the speed of the pump be greatly increased, the sudden stopping at the end of the stroke causes 'water-hammer,' which is liable to wreck the water-column.

By the use of the crank-engine and fly-wheel, these difficulties are to a considerable extent overcome. With the heavy fly-wheel to absorb the surplus power, a higher steam-pressure can be used at the beginning of the stroke, and then cut off so as to utilize its expansive power. Being crank-driven the pump-rod starts slowly and stops slowly, thus avoiding the shock incident upon the sudden stopping of the stroke. From the different articles which have appeared in your magazine, it is evident that this improvement—and improvement it must be—since it has such obvious advantages, has many champions. The great drawback to both the above forms of pump is the heavy rods and beams, which not only make a cheap installation impossible, but as their inertia has to be overcome twice during such stroke, greatly decreases the pump's efficiency as a whole. As these moving parts weigh from two to six times as much as the column of water to be raised, this loss of power will be seen to be considerable. The direct-driven steam-pump overcomes this trouble, but the advantage gained is offset by the loss from condensation in conducting the steam from the surface to the underground pump-engine. This loss can be minimized by careful packing of the steam-pipe, but is present to a greater or less extent in all underground pumps. When this type of pump is constructed with compound condensing-engine, it gives a high efficiency. It throws a continuous steam, which makes a smaller, lighter water-column possible, as the pounding is avoided. Owing to the great number of different classes of steam-pumps on the market, one can be had that will fit almost any circumstances or conditions. It cannot be questioned that the steam-pump has the advantage in first cost, and adaptability, efficiency, and durability depend entirely on the choice of pump, and the care used in its installations.

The present practice in pumping is to avoid steam altogether, wherever electric power is available. The new electric-pumps now being installed at the Ward shaft at Virginia City, Nevada, are to cost $125,000. They are of the plunger type, with automatic poppet-valves, and will have a capacity of 1600 gal. per minute against a head of 1550 ft. Pumps of the same type have been tested and shown to have an efficiency of 90 to 93.6%, and a combined efficiency for both pump and motor of from 78 to 84.4%. The valves and wearing parts are all arranged so that they can be easily removed and replaced. The space which the pump will occupy is small, so that from any point of view a comparison between this style of pump and the old Cornish pump would not be to the advantage of the latter.

San Francisco, July 20.

Sumner E. Brown.

Slime Filters in Mexico.

The Editor:

Sir—In a recent number of the MINING AND SCIENTIFIC PRESS I note in the news items from Pachuca that the installation of Moore filters by the Compañía de San Rafael is given to your readers as putting an end to the rights of the Moore people versus Butters. It hardly seems square to the man in the street that the reading columns of a paper with such a standing as your own should set forth this class of information when there are a whole lot of us who are users of the Butters filter and have gone into the matter very thoroughly through counsel both in the United States...
and here with results that apparently quite justify us in installing additional Butters filters. What do you think about it?

C. W. Van Law.

Guanajuato, Mexico, July 16.

[We have no opinion as to the rights of either contestant in the regrettable legal controversy over slime-filter patents. The opinion of our correspondent was accepted as a local interpretation merely, and has the interest which always attaches to a local point of view. That is worth knowing by both plaintiff and defendant. We have admitted matter to our columns advantageous, so far as mere publicity goes, to both parties, and we are ready to continue chronicking the results obtained by both without preference.—Editor.]

Divining Rods.

The Editor:

Sir—I would greatly appreciate a little information in regard to the so-called divining rod, or switch, and the apparatus for finding orebodies. No doubt you will laugh at such a request, but I am often surprised at meeting people credited with some sanity, who express absolute faith in this method of prospecting. Some years ago, in the Cripple Creek district, I had opportunity to watch the work of one of these so-called wizards, and noted that on each of the several occasions where the ore failed to materialize as forecast, it was due to the orebody being 'capped,' and that the ore did exist, as the instrument indicated, but that no idea could be given as to the depth necessary to go to reach it; simply that it was there. In a supposedly 'technical' paper, published on the Pacific Coast, appears an advertisement stating that gold-bearing veins can be absolutely discovered with the aid of this instrument, and correspondence with the firm elicits the statement that 'all mineral discoveries made subsequent to the discovery of the Mizpah mine of Tonopah, Nevada, were made with this instrument.' This statement is without doubt, very unlikely to be true, still it is believed by a number of people.

My reason for sending this letter is that I am frequently asked my opinion of the divining rod, and while I have no faith in it, would value opinions from others. It is a fact that there are disciples of this method of mining, and frequent ventilation of the truth is desirable to stop the expenditure of money which is constantly being made in following up this foolish practice.

Edwin S. Giles.

Rhyolite, Nevada, July 16

Professional Ethics.

The Editor:

Sir—Your scholarly editorial, 'Professional Ethics Again,' in your issue of July 18, sets forth lucidly certain tenets often lost sight of, and constitutes a notable contribution to the literature on the subject. Mueh has been written concerning what the mining engineer should not do, but a clear statement seems lacking as to what he should do. What we expect of an engineer is that he shall have knowledge and experience in that particular branch of work; that he shall have been trained to observe; that he be a man of integrity who will shirk no trouble to obtain all possible facts that might assist in arriving at a just conclusion; that he will distinguish clearly between deductions based upon his own knowledge and such as are based upon information received, and will so report. If he make use of such information, then to the extent which he uses it, he endorses and is responsible for it. On this point in particular we are apt to slip up. The statement of facts and conditions should cover the ground so completely that another engineer may deduce his own conclusion therefrom, even to an opposing one. One engineer may in his conclusions rely chiefly on one set of conditions, but another with larger experience may place a greater weight upon another set, both being duly and correctly represented. A report should be written out fully and completely, embodying in it all the ideas on the subject-matter pro and con, and then being sure that nothing has been forgotten it may be cut down and confined to such points as enter into discussion. Finally the engineer should cross-examine himself, on every sentence, and so far as the data will admit of definite advice this should be given in the most explicit manner.

San Francisco, July 22.

Howard D. Smith.

Slime Filters and Patents.

The Editor:

Sir—In your issue of May 16 there is a communication from Askin Nicholas in regard to compressed air being used for keeping the filtering medium in a slime plant porous. Not having seen the previous correspondence, I am at a loss to know the exact method Mr. Nicholas refers to and the date that he is trying to establish, but if he will look in the Transactions of the American Institute of Mining Engineers, Vol. 31, he will see that in 1900 I used air-agitation in combination with bromo-cyanogen treatment. The slime I was treating was so heavy that I could not get the solution to percolate, but after many experiments I hit upon compressed air, and it worked perfectly both for distributing the pulp uniformly and for keeping it porous during treatment. This application of compressed air was original with me at that plant, but I understand that others had used a similar process elsewhere some time before.

Wheeling, West Virginia, July 14.

S. H. Brockunier.

A sixty-six story building has been planned for the Equitable Life Assurance Co., to replace its antiquated structure on lower Broadway, in New York. The total height of the building will be 909 ft., or only 75 ft. less than that of the Eiffel Tower. The main part of the building will be only 34 stories or 489 ft. high, but will be surmounted by a two-section tower having 28 stories and a 4-story cupola.

The highest mine in the world is the Santa Barbara, Bolivia, South America, which is at an altitude of 18,000 ft. above sea level.
GEOLGY OF THE MINING DISTRICTS OF CHIHUAHUA, MEXICO.

Written for the Mining and Scientific Press
By Rufus M. Bag, Jr.

The literature upon the geology and mining industry of Chihauhua is extremely limited, although many brief outlines of its geological features have been published by mining engineers. Not only are systematic reports lacking, but no correct detailed geographic and geologic maps of this important area exist. Even the Government postal, telegraph, and commercial maps of Chihuahua are incorrect in many particulars. Recent developments of ancient mines known as *antiquas*, together with the discovery of new ore deposits of phenomenal richness, have resulted in the investment of large sums of foreign capital in the district. Consequently public interest in mining enterprises in the State rapidly increasing.

The history of mine development in Mexico dates from the conquest of the country by Cortez in 1520. Six years after the original battle which decided the future of Mexico, mines were opened in Guanajuato, and very rapidly thereafter mining began throughout widely extended portions of the country. Fortunately the taxes collected for Spanish revenue from these mines were recorded in the public documents, and these archives bear witness to the richness of some of the early discoveries. On October 4, 1523, Mexico threw off the Spanish yoke, and a Federal Government was instituted. Thirty years later, Texas seceded, and the Mexican war resulted. Through her defeat Mexico lost to the United States almost one-half her original territory.

Chihuahua is one of twenty-seven separate States of Mexico. It comprises an area of 83,746 square miles, which is approximately that of Utah or Kansas. Its northern boundary adjoins Texas and New Mexico, Sonora and Sinaloa lie to the west, Durango on the south, and the State of Coahuila borders it on the east.

The city of Chihuahua was founded in 1691, and its subsequent growth was due to the opening of the famous Santa Eulalia silver-lead mines, 18 miles southeast of the city, in the year 1703.

The surface relief of the State is divisible into two main types of topography, plateau and plain in the east and rugged mountains in the western Sierras. The Mexican Central railroad runs south to the city of Chihuahua, 226 miles from El Paso, on a line near the western plateau border. The general elevation of the plateau cannot be far from 5000 ft. above sea-level, and its average width in Chihuahua is about 100 miles. On the western side of the plateau the Sierra Madre rises abruptly and extends westward for some 200 miles, reaching over into Sinaloa and Sonora. Robert T. Hill describes this eastern portion as belonging to one of the two great American deserts which he calls 'Chihuahuan,' the other being the 'Sonoran.' The latter includes part of Arizona and California, while the Chihuahuan includes portions of Coahuila, Texas, and New Mexico.

The plateau region of Chihuahua is broken by a series of low ridges and small mountains which lie east of the Mexican Central railroad, trend north and south, and cross the entire State. This eastern area is not as extreme a type of desert, if we except its northern and eastern portion, as in the Sonoran, which difference is believed to be due in part to its greater elevation. Stretches measured by thousands of acres are suitable for grazing, and what is said to be one of the largest cattle ranches in the world lies along the western border of the plateau, 25 to 30 miles in width, parallel with the Mexican Central railroad. Until recently there has been little mining done in this belt. Twenty-five miles north of the city of Chihuahua, and thence eastward, there are, however, a number of promising silver, copper, and zinc properties in the Cretaceous limestone, which are being developed. The mountainous portion of the State is composed of late volcanic rocks belonging chiefly to the acid series. Rhyolite, trachyte, andesite, with various breccias and tuffs form the bulk of the ranges. These formations extend westward for nearly two hundred miles, reaching over into Sonora, where they constitute the eastern boundary of the Sonoran desert.

The Chihuahuan mountains are characterized by broad peaks and ridges, deep narrow canyons, and rough broken country into which the streams have cut gorges and carved out erosion-bloeks of large dimensions. A typical view in the Sierra Madre is presented herewith, showing the contrast between timbered and barren areas. Such deeply eroded country is common throughout the western portion of the State, along the line of the Kansas City, Mexico & Orient railroad. The crests of the ranges have an altitude ranging from 7000 to 8000 ft. above sea-level. Nearly all this portion of Chihuahua is covered by heavy timber, some of it being of commercial value. A large portion of this belongs to the timber reserve of Mexico. Until recently it has been impossible to obtain concessions from the Government upon this forest reserve, although the remaining lands of the State have been for sale at a nominal figure. The rough broken topography of the country makes travel extremely difficult. The same rugged conditions must prevail throughout the Sierras elsewhere, for although thirteen railroads have built westward into them, only one road has as yet crossed the range. The Kansas City, Mexico & Orient railroad, one of the latest to make the attempt, is still in the heart of the mountains.

As the volcanies make the mountain region, so in Chihuahua the sedimentary series underlie the eastern plains. These are largely Cretaceous, and consist of limestone and intercalated sandstones which extend along the eastern and southern border of the State. The Santa Eulalia, Almoloya, Terrazas, and Coyame camps owe their prosperity to the deposition of ore in solution-chambers of these rocks. Under the undoubted Cretaceous beds is a lower series of rocks which is probably earlier than Cretaceous. This consists of an immense thickness of sandstone, shale, and limestone, dipping at high angles, and exposed for some 70 miles northwest of Parral to
near Chihuahua, a short distance east of the Conchas river. Near the base of the series is a bed of white conglomerate 60 ft. thick, standing nearly vertical, trending north and south, and carrying in one place across its entire width gold to the value of 80c. per ton. Fossils are very rare in these strata. A ride of three days over this area failed to show any characteristic fossils by which the age of the rocks could be determined. To the southwest, R. H. Burrows has discovered Jurassic forms, *Rhyacobella*.

The second type of pyroclastics occurring in this portion of the district consists of very coarse conglomerate masses in which the pebbles are frequently so large and angular that the rock is more nearly a breccia than a conglomerate. This formation is the "Navosaigame" of Messrs. Hill and Hovey. These beds are poorly stratified and roughly sorted. They overlie the older volcanic formations and in turn are themselves buried beneath later rhyolitic and andesitic flows and tuffs.

Of far greater importance than the two pyroclastics just described is the unstratified tuff covering hundreds of square miles of the more elevated regions of the southwest portion of the State. The Navosaigame of Messrs. Hill and Hovey does not appear to extend very far south of Ocampo and points west of them, while the tuff capping much of the country to the south of Ocampo is very extensive.

It is largely due to this deposit that the various mining centres in western Chihuahua are so widely separated. It is not that no ore exists between the mineral zones, but rather that the veins which do exist lie deeply buried from sight under this cap of tuff. The large number of mineral-bearing veins which have been found wherever the true volcanics occur leads to the inference that others may exist elsewhere below the surface-capping.

*(To be Continued.)*

An explosion of gas July 15 in the Williamstown colliery of the Summit Branch Mining Co. resulted in the death of seven miners and serious injury to ten others. The explosion is believed to have been caused by one of the men lifting the ganze of a safety lamp immediately after a shot had been fired.

---

THE JOHN A. ROEBLING MONUMENT.

A monument to the late John A. Roebling was unveiled at Trenton, N. J., on June 30. The statue was erected by the Roebling Memorial Association, the expense being borne mainly by the citizens of Trenton and Roebling. The afternoon of the day was observed as a holiday, both in commercial and official circles, and fully 15,000 people congregated in Cadwalader Park to witness the dedicatory services and the unveiling. Preceding the ceremony, a parade of 6000 employees of the Trenton and Roebling plants, of the John A. Roebling Co. marched through the streets of Trenton to Cadwalader Park. The principal event of the day was the address of Henry D. Estabrook, general counsel of the Western Union Telegraph Co., at New York. The oration gave an interesting account of the life and character of Mr. Roebling, and is therefore reproduced in part herewith:

Those who knew him best affirm that the statue of John Augustus Roebling, which you, the citizens of Trenton, have here and now erected to his memory, is a true and faithful likeness. But it is more. Through some Promethean fire that flames once in a life-time in the heart of genius, the sculptor has "in this rough work shaped out a man."

I am expected by those having these ceremonies in charge to translate into words what the sculptor has so admirably expressed in bronze, namely, the type and quality, the idiosyncrasy of your famous townsman. But words are all too plastic for such a task. As if his nature had been subded to what it worked in, the Ironmaster of Trenton was a man of iron. Iron was in his blood and sometimes entered his very soul—a man of iron, with the virtues of iron and the pecanns of iron to his account.

John Augustus Roebling was born in June, 1806, in Mulhausen, Germany, in the State of Thuringen. Mulhausen is an old walled town, founded in the year 800. The wall was really built to keep people out, though why anybody should want to get into Mulhausen is a matter of wonderment, after reading a description of it.

To a man like Polycarp Roebling, father of John Roebling, the prescriptive life of this old German village was by no means irksome. He kept a tobacco shop and managed to smoke as much tobacco as he sold. Smoking in Germany, you know, is a solace, whereas in America it is an employment. So Polycarp loved Mulhausen and lived and died there, in spite of his son's efforts to lure him to America. The mother differed greatly from the father in character and disposition, and John A. Roebling was the son of his mother. She was a woman of tremendous activity, mental and physical. Deep in her soul she nourished ambitions which became tragedies through very hopelessness. She had borne four children, three sons and a daughter, but it was not until her youngest child, John, had displayed mental qualities to distinguish him even in the eyes of strangers that there dawned upon her the full significance of motherhood. Henceforth ambition had but one goal, life but one object—the education of her boy.

Thus it was that John Roebling was enabled to graduate from the Royal University of Berlin, after a course at the Pedagogium of Erfurt; and thus it was that when, shortly thereafter, he sailed for America, he carried with him a patrimony large enough to insure his establishment.

John Roebling set sail for America in the year 1831, and landed on our shores a young man of 25, seemingly equipped for any battle that awaited him. He was a most accomplished gentleman. If a wise-acre had predicted his failure it would have been on the very ground that he was too accomplished, that his learning and talents were too varied ever to focus in a particular vocation—especially the vocation of a farmer, which he had deliberately chosen. Nevertheless he had chosen to become a farmer. He had graduated from the greatest university in the world, as an architect and engineer. He was a scholar of wide reading; he was a philosopher of the transcendental sort, whom an American 'hustler' would shy at as a crank; he was a musician of rare skill and temperament; he was the master of three languages, German, French, and English; but what had all this to do with farming?

And yet he had chosen well, at least for the time being. In the first place his choice had led to a thorough study of American history and geography. His knowledge of the topography, climatic and political conditions, the advantages and disadvantages of the different States in our Union was as accurate as if he had personally visited every one of them. The reasons set forth in his diary for settling as he did are most convincing. In the next place, he forthwith invested all his money in desirable lands at cheap prices, thus preventing its dissipation in some visionary enterprise.

The lands selected by him were in the western part of Pennsylvania, Butler county, about 25 miles from the new town of Pittsburg. Here he and a few of his compatriots purchased some seven thousand acres at an average price of $1.37 per acre, and founded the village of Germany, afterward called Saxonburg.

I may as well admit that John Roebling never became a first-class farmer. He made a living, to be sure, but it was a meagre living, and if by good luck he got a little money ahead he was sure to give it to some German emigrant in worse plight than himself.

One day it occurred to farmer Roebling that he might patch out his income if, between crops and during the winter, he could obtain employment as an assistant engineer in making surveys, building canals and dams for slack-water navigation, and such like work that was going on in his vicinity. His services were readily accepted, his real merits were soon recognized, and it was not long before his knowledge and skill were in actual demand. Henceforth the farm was practically abandoned so far as John Roebling was concerned.

In his work around the canals he had long noticed the heavy clumsy ropes, made of Kentucky hemp, used to haul canal boats over the portage railways. They were costly and short-lived and a considerable...
item of expense. John Roebling opined that if a rope could be made of wire flexible enough to be wound on a windlass, it ought to cost little more than a hempen cable and would possess greater tensile strength with one-fourth the diameter. Moreover, German ought to do in America. At all events the idea was worth a trial.

So he built a rope-walk on his farm at Saxonburg, purchased a quantity of wire deemed suitable for his purpose, instructed his friends and neighbors in

The Roebling Statue at Trenton, N. J.

(Wm. Cooper, Sculptor)

it would outlast a dozen ropes woven from vegetable fibre. No one in America had ever made a wire rope nor ever seen one. Roebling himself recalled an item in a periodical sent him from Mulhausen, to the effect that some German inventor had produced a wire rope, and he concluded that what an indigenous German could do in the fatherland, a transplanted

the art of rope twisting, and actually fabricated a wire rope that surprised his most buoyant expectations. It was a remarkable achievement and almost made him famous. But he did not stop here. John Roebling's inventive mind evolved an idea, having its origin in a memory.

While yet a student at the university he saw for
the first time a bridge suspended by chains spanning a small stream called the Regnitz. He had studied this structure, sketched it, and made it the subject of a thesis. Now he recalled his youthful essay and bethought him that if a cross-river aqueduct were suspended from wire cables (so much stronger than chains) it would eliminate piers and posts and other obstructions and leave the river to flow at its own sweet will. He laid his plans and calculations before the engineers of a casual company about to cross the Alleghany river at Pittsburg, frankly admitting that what he proposed to do was without precedent, and in Germany would doubtless be frowned upon. But he insisted that his figures were correct and spoke for themselves, and that the advantages to be gained justified some risk. In short, that his scheme ought to appeal to the American spirit of shrewd adventure and daring enterprise.

He was ordered to do the work, and set about it knowing that the outcome would either place him in the forefront of American engineers or ruin him forever. The undertaking was a success and led to many commissions of like kind, several of these suspension aqueducts being still in use, unimpaired, and seemingly good for all eternity.

Now a layman can see that a suspension aqueduct is nothing less than a suspension bridge, carrying an enormous load. John Roebling recognized the fact and pondered it; the whole world knows the results of that cerebration!

Before he had completed his first suspension bridge over the Monongahela, Mr. Roebling realized that he must have shops and machinery and possibly mills for drawing his own wire, and he further realized that Saxonburg was not a suitable place for such a plant. On the advice of his friend, Peter Cooper, whose iron foundries were at Trenton, he visited this Quaker city, studied its advantages, purchased a quantity of ground, and in 1849 removed his family from Saxonburg here, the journey requiring seven full days—accomplished now in almost as many hours. Mr. Roebling was the architect of every building of his new plant, and the inventor and designer of nearly every piece of machinery that went into those buildings; for it was not until years afterward that he could be persuaded to employ an assistant engineer or draughtsman.

His planning of the Kentucky bridge, which was never built; the actual erection of the Wheeling bridge, the Cincinnati bridge, and even the wondrous bridge over Niagara Falls, were simply preliminary training for the monumental work that was to cost him his life while crowning it with glory.

When John Roebling presented his plans for the Brooklyn bridge the engineers of the whole world scoffed at them as audacious and absurd. If, said they, he should succeed in spinning his iron filaments over so vast a stretch, what useful purpose would he accomplish? Poof! Roebling's tangle of wire was a web to catch flies—he was routing the fate of Arachne in the fable! It was, in sooth, a work of unexampled difficulty; looming, portentous, titanic! He fought his detractors inch by inch for the right to try, defending his ideas with such vehemence and courage that finally this right was given him. The great work, begun by himself after his own designs, was completed by his son. It is called today, in the candid admiration of mankind, The Eighth Wonder of the World.

Originally planned for a calculated load with a margin of safety, the exigencies of traffic have long since burdened this noble structure many times beyond its promise; and yet, within the last few weeks the board of experts appointed to examine its condition report that it is safe and unharmed, and, if possible, has grown stronger with use. Luckily for the people of New York, John Roebling's promise was always less than his performance.

But the Brooklyn bridge is more than a crowded highway; it is a thing of art, beautiful in itself. From the bedrock of a mighty river, one hundred feet below its surface, bastions of masonry leap toward the clouds and kindle in the distance like shafts of light. The tempestuous festoon that seems to cling to them floats in the air—an incredible gossamer woven in a dream. Yes, Brooklyn bridge is beautiful! All the latent poetry of the mathematician and in its highest reaches mathematics becomes divinest poetry—all the ethesicism of the architect; all the musician's sensitiveness to harmony; all the mysticism of an idealist philosophy: whatever of faith, feeling, reverence John Roebling cherished in his heart, was here voiced like a ringing cry. As if conscious of his pending doom his genius stands embodied in this final form—an inspiration visible—a soul's bid for immortality!

CINNABAR IN NEVADA.

American canyon drains the eastern slope of the Humboldt range and is about 26 miles south of Mill City. This mountain range trends nearly north and south, and American canyon takes an easterly course, being about three miles in length. The bed of this canyon was worked extensively for placer-gold from 1882 to 1900, the proceeds of these operations aggregating over a million dollars. In the course of this considerable cinnabar was found. It occurs in limestone at the contact of the latter with an intrusive diabase. This vein is well defined and spreads into the diabase to some extent. The cinnabar occurs in shoots, and the fact that nuggets of gold have been found in the lode-matter supports the belief that much of the placer-gold of the canyon came from this lode as it was eroded. The same lode can be followed into the bed of the canyon at its southeastern extremity. The northwestern extension of the lode passes into the hill and there outcrops high above the bed of the canyon. Following along the strike of the upper end of the outcrop for 1400 ft. a series of openings has been made, in all of which cinnabar has been found, occurring in a gangue of lime carbonate and quartz, said to average above 3% cinnabar. Cinnabar is also found on the western slope of the Humboldt range, occurring here in limestone and serpentine, in irregular bodies, and carrying from 2 to 4% cinnabar. This deposit is six miles south of Humboldt House.
The Yellow Jacket Mine, at Gold Hill, is the first mine on the Comstock Lode to attack the problem of low-grade mining. The mill was completed in February, 1908, and since then has been regularly treating about 180 tons per day. The management is attempting to solve the problem by simple concentration. The men in charge take the view that they can concentrate ore that assays as high as $8 per ton and leave less than $2 in the tailing, and they maintain that their $2 tailing cannot be cyanided at a profit. On the other side of this milling debate is Charles Butters & Co., Ltd., who have 20 stamps, two tube-mills, and a 250-ton cyanide plant in the canyon two miles below Virginia City. In March, 1908, this Company obtained leases on the Chollar and Potosi croppings, and has since been doing considerable work in opening up the two old surface-tunnels and their many drifts. Mr. Butters appears to be preparing to work ore that assays as low as $7. He must pay 18% of the bullion-value to the lessors, the usual 4% royalty to the proprietors of the Sutro tunnel, and also the local taxes. Therefore he will have to mine, mill, and cyanide for less than $5 per ton, in order to make a profit on $7 ore with 90% extraction. His work will be watched with a double interest, for it is understood that he will undertake to reduce expenses by cutting out concentration, with its attendant shipping expenses, as much as possible, and will substitute cyanidation of the sulphides. Low-grade mining opens new possibilities on the Comstock, and there is an immense tonnage awaiting a solution of the problem. The Yellow Jacket mine has a bullion-record of $19,000,000. The lower levels were flooded in 1882, and the mine was then worked in the upper levels for the lower-grade ore which had been passed by in the bonanza days. The water now stands a little below the 1400-ft. level, but the mine is not open below the 1100-ft. level. In 1906 H. L. Slosson and associates bought control of the mine on the Stock Exchange, and took over the management from the Morrow-Sharon interests. The latter gentlemen had previously held undisputed sway in Gold Hill, but they did not own the stock of the mines that they managed. The new owners are now working the low-grade ore in the out-croppings, and are preparing to work the 'gold vein' between the 1100 and 1500-ft. levels, until such time as the water is lowered and access can be had to the deeper workings. Before acquiring control of the mine Mr. Slosson had a verbal option on the Yellow Jacket dump, which was supposed to contain 200,000 tons that would yield a profit of $1 per ton; but the promotion missed fire. The mill has been placed convenient to the dump, and about 2000 ft. from the hoist; but silver has fallen from 70c. per ounce to 52½c., and the dump is not now so highly cherished. Formerly Mr. Slosson sold Kinkade mills for Henshaw, Bulkley & Co., of San Francisco, and when he acquired the Yellow Jacket property he had the courage to swallow his own prescription—the mill he erected has twenty of them. The Kinkead mill at Goldfield has passed to the cemetery; and when Charles Butters & Co. leased the Kinkead mill in Virginia City belonging to the Best & Belcher Co., the operation was said to have been accompanied by
costly repairs and extensive profanity. But the inventor seems able to keep his machinery in a better humor. The Kinkead Mining & Milling Co. began operating on the C. & C. dumps in Virginia City, and for several years past has been running without intermission on ore from the Ophir. The new type of crusher in the Yellow Jacket has also run for four months now without trouble. Mr. Kinkead superintends both of these installations. The Kinkead mill consists of a bowl, 40 in. diam., and an inverted mushroom for a muller. The stem is given a small eccentric motion, at 210 revolutions per minute; the ore is fed in through a hole in the centre of the muller, and discharges through screens on the periphery. The total weight on the muller, including the shaft, is about 5000 lb. The original claim for the mill was that it did not slime the ore; but there are considerable quantities of silver sulphide floating on the vanners when working the Ophir $30 ore.

At the Yellow Jacket the ore from the breaker is ground to 40 mesh in the mills, and is then classified into three parts, in home-made box-classifiers, one for each two mills. The concentrating room has 30 six-foot, plain-belt, Risdon-Johnston concentrators, in three rows, each row taking one size from the classifiers. In April 1908 the mill treated 4632 tons of ore assaying from $5 to $7 per ton, and extracted 178,000 lb. of concentrate. The value in the concentrate was 75% gold and 55% silver. The concentrate was 52 into 1, and the extraction was about 70%. The tailing assayed from $1.25 to $1.86 per ton and the average was close to $1.75. In May 1908 the mill treated 3472 tons, and all but 750 tons was oxidized ore from the outercrop. One-third the value was silver and two-thirds was gold. The extraction by concentration was 68%. The concentrate generally assayed about $1.75, but one shipment went $379. The expenses of mining and milling were a little less than $18,000 or $3.30 per ton. Allowing for smelter-deductions, the cost was about $3.50 for a 68% recovery. The milling and concentrating cost about 75c. per ton, and the cost of shoes and dies, after selling the scrap, was between 12 and 16c. per ton. The cost of marketing the concentrate, including smelter-deductions, amounted to 54c. per ton of original ore. The breaker runs two 8-hr. shifts. The mill runs three shifts, with two men at a time at the mills and two at the concentrators. Mill foremen work one shift only. The mill and rock breaker averaged, by meter, 115 hp. for the month, at a cost of $5 per hp.-month. The mill cost when completed, $82,000, of which $8000 was expended for excavation.

There are three classes of ore in the mine, and unfortunately they are not equally susceptible to concentration. The sulphide-silver ores yield about 70%. The oxidized outercrop yields between 60 and 70%, and only 50% of the silver content is extracted. The 'gold vein' on the foot-wall, has practically no silver, and yields by concentration fully 80% and sometimes as high as 88. Each month the drop-boxes below the Kinkead mills are cleaned out and the sand is panned with quicksilver. About $1200 is thus obtained, which is nearly all gold. If the simple concentration-process adopted by the Yellow Jacket has any advantage, it is evident that it can hold that advantage only below a certain limit, which is determined by the cost of cyaniding. The Kinkead Mining & Milling Co., at Virginia City, is working $30 ore from the Ophir, using Frue vanners, without classification, and also a small canvas plant. The concentration is 33 into 1, and the extraction by concentration for six months has averaged about 71% on the mine-cars samples, and 75% on the mill-pulp assays. The gold extraction was 84% and the silver 59, based on battery assays. The tailing assayed from $5 to $8 and were sold to the cyanide plant of Charles Butters & Co. The Yellow Jacket has not given the final solution of the problem of working the immense quantities of low-grade ore in the Comstock veins, but it is the first mine on the Lode to mine and mill its ore at as low a figure as $3.50 per ton.

A. M. M., Millspaugh, California: Amphibolitic schist, derived from a basic igneous rock; shows some pyrite.

F. J. S., Goldfield, Nevada: Hornblende-andesite altered by carbonate waters that deposited metallic sulphides in the rock.

J. V. R., New Denver, B. C.: Highly altered rock, probably andesite, decomposed by carbonated mineral waters and filled with calcite and pyrite.

W. C. R., Nashville, Arkansas: Thoroughly decomposed plutonic (crystalline) igneous rock, probably originally a gabbro.

W. S. S., Silver Peak, Nevada: No. 1, quartzite; No. 2, decomposed obsidian showing iron spots; No. 3, garnet; No. 4, obsidian, showing effect of earth movements.

H. G. G., Gold Circle, Nevada: No. 40, andesite, partly decomposed and leached of most of its iron; No. 41, pitchstone—volcanic glass; No. 42, nearly fresh andesite; small traces of a mineral looking like cinnaabar were present but in too small amount to test; No. 43, nearly fresh andesite showing flow-planes; No. 44, andesite, altered and showing flow-planes; No. 45, altered andesite.

C. E. S., Sweetwater, Nevada: No. 1, missing; No. 2, quartzite; No. 3, schist, derived from basic igneous rock, probably andesitic tuff; No. 4, sericite silicious schist, partly decomposed and filled with limonite seams containing traces of sulphides; No. 5, silicious schist with traces of sulphides nearly completely removed; partly stained with limonite; No. 6, impure mixture of iron silicate, limonite, calcite, and some silver; No. 7, biotite-andesite; No. 8, fluorite on quartz and stained with earthy oxide of manganese.
CYANIDATION IN MEXICO.

Written for the MINING AND SCIENTIFIC PRESS
By FRANK J. HORDON.

In the early part of 1906 I made a number of laboratory experiments on silver-gold ores from the State of Sinaloa, Mexico. The results of these experiments demonstrated that silver could be successfully extracted from its ores by the use of a comparatively large amount of strong cyanide solution. A small leaching plant was erected, using filter-vats each having 10 tons capacity. The ore used in the experiments contained 15 oz. silver and 0.15 oz. gold. In order to secure an even leach it was found necessary to remove some 15% of its weight of slime, containing approximately 20% of the assay-value. The ore was crushed to pass 40 mesh. A 10-day leach, with 0.5% KCy solution, extracted 84% of the silver and practically all of the gold. The weight of solution used, in proportion to the weight of ore, was three of solution to one of ore. The strength of the solution was kept up to 0.5% for the entire period, and the cyanide consumption was about 3 lb. per ton. Ten pounds of the local slaked lime was intimately mixed with the charge before starting the leach. The gold and silver was precipitated from the solutions on zinc shaving. The separated slime was treated in the laboratory with various strengths and amounts of solution, resulting in a high extraction of the silver, when using four, or more, times the weight of dry slime of 0.2% Cy solution. The silver in the ore was nearly all argentite. The gangue contained 90% silica, about 2% iron pyrite, 0.3% hematite, traces of manganese as pyrolusite, 0.5% aluminium, 3% lime as carbonate, and no copper. As silver had not before been cyanidized with any degree of success, I considered this application new, and almost equivalent to the invention of a new process. I am still under the same impression, and believe that successful cyanidation of silver ores in Mexico began with the installation of that small leaching plant. It was operated for several months, and several clean-ups were made, which checked closely with the estimates from assays. The precipitate was melted in a crucible, and a bar of bullion produced assaying 830 points fine silver and 10 points gold.

At that time I was in charge of a mill and pan-amalgamation plant that was extracting about 80% of the silver and 70% of the gold content, and ahead of the treatment we were losing about 10% in slime. I tried to persuade the company to change to the cyanide process, but they were afraid to make the experiment, regardless of the fact that I had proved by bullion-returns that it was good business to do so. The importance of the tests lay in the discovery that silver could be successfully extracted from its ores by the cyanide process (in the absence of base-metal interferences in the gangue) if ground sufficiently fine, by subjecting the sand to a leach, where-in the silver was brought in contact with 30 times its weight of potassium cyanide, and that silver could be extracted from the slime if the latter was agitated with 16 times its weight of potassium cyanide. In either ease the strength of solution did not appear to be an important factor. To date I find this to be invariably the rule, except where the silver occurs as chloride or bromide. In that case the proportionate requirement of cyanogen is much less.

In the year 1898, I installed a plant of 1000 tons per month capacity in the State of Durango, converting it from a roasting-hyposulphite-lixiviation plant. The ore was dry-crushed to pass 16 mesh, and leached in vats having capacities for one hundred 40-ton charges. The extraction was 77%, the resulting bullion being 940 fine silver, and 18 points gold. Finer grinding would not permit an even leach, consequently the low extraction, which was about equal on both gold and silver. In January 1899, I began building a slime-agitation plant in Durango, and had it operating in May of the same year. Here I had my first opportunity of practically demonstrating my 16 to 1 theory for silver extraction by agitation. The slime treated contained from 14 to 25 oz. silver per ton, and the plant-capacity was 7 tons daily. The charges, of about 2300 lb., were agitated four hours with four times their weight of 0.2 to 0.3% KCy solution, and 12 lb. slaked lime, and were then drawn into settling-vats. After settling, the solution above the charge was decanted into a clarifying tank, and another full charge of solution was added to the slime-charge under treatment. After its decantation, about 2500 lb. of wash-water was added, and this was decanted after settling. The decanted solutions were passed through zinc-boxes and returned to the upper sump-vat for re-use. Before treating, the slime was collected in settling-vats, from which it was removed to a large patio (yard) and sun-dried. This drying made the water-wash possible, reducing the mechanical loss of cyanide in the discharged residues. The chemical extraction in the agitation-period averaged about 92%. 80% of the extraction was recovered by the first decantation, 80% of the remaining twenty by the second, and 50% of the remaining four by the water-wash decantation, resulting in 98% recovery of the chemical extraction or silver in solution. The plant is still in operation, and the extraction by bullion returns, since the installation of the plant has been the same 90 per cent.

In the latter part of the same year (1899) E. A. H. Tays installed a successful plant for slime treatment at San José de Gracia, in the State of Sinaloa. In the early part of 1907, I tested ores and designed a plant, for another Durango company, that was installed and is still in very successful operation. A variation here from my previous practice was that of concentrating ahead of cyanidation. After concentration, the sand and slime are separated, the sand being leached, and the slime agitated with cyanide solution. About that time, Messrs. Corrigan and McKinney erected a 40-stamp mill with a cyanide annex at Coneño, Chihuahua. Concentration preceded cyanidation, and the sand and slime were treated separately. Difficulties were encountered in settling the slime, and solution is recovered from the treated residue by a special filter-press designed by Mr. Corrigan. In 1898 one plant in the Territory of Tepieé, and another in the State of Michoacán, substituted cyanide solutions and zinc precipitation for hypo-
sulphite lixiviation on chloridized roasted ores. The Michoacán treatment was changed under my direction in 1901 to amalgamation, concentrating, and cyaniding the raw sand and slime separately. The change resulted in a slightly higher extraction, and a decrease in treatment-cost of $5 per ton.

In 1901, a 2000-ton per month plant was installed in the Territory of Tepic, under my supervision. The ore is crushed in Bryan mills, concentrated on Wilfley tables, the sand leached and the slime agitated with cyanide solution. The silver recovery averages 88 per cent.

During the years 1900-01-02-03, several small plants were installed in the Republic by myself and others, for treating silver and silver-gold ores. The majority of these installations are commercial and technical successes. The ore treated with cyanide daily in Mexico, was at the end of the year 1903, about 500 tons. This refers only to those plants treating ores where the silver predominates over the gold content, in value. The most important application of the process since 1903 has been in the district of Guanajuato, where about 2500 tons of ore are being treated daily. This will be increased within in eighteen months to 6000 tons, the installations now being under way. There are ten mills in operation, with capacities varying from 1000 to 1500 tons per month, most of them of my own design. The general practice in the camp is to crush, concentrate, and cyanide the sand and slime separately. Three of the mills, however, amalgamate the gold before concentration. The average total silver saving of all the plants is near 90 per cent.

During the period 1903-1907, a number of important plants were installed in the Republic. The Chas. Butters Co., is successfully operating a large plant near Panuco, Sinaloa; the Palmerejo Co., one in Chihuahua; the Real del Monte Co., a large plant in Hidalgo, and a number of other plants, of more or less importance, are operating in the States of Chihuahua, Jalisco, Durango, Sinaloa, Zacatecas, and Querétaro. Also a number of others are in the course of construction, the total tonnage now treated daily in the Republic being about five thousand. The adoption of the process has created a new industry in Mexico, as 90% of the ore treated by it could not be reduced profitably by any other known process. It has almost entirely superseded the patio and pan-amalgamation methods. Invariably a larger percentage of silver in the Mexican ores can be extracted by cyaniding, at from one-fourth to one-tenth the cost of amalgamation. This may seem like a broad statement but it is nevertheless true. The average cost per ton of cyaniding crushed ore in the Guanajuato district is about $1.25 and in some of the larger plants it is less than 75 cents.

In considering the adaptability of the cyanide process for the extraction of silver from its ores, the question arises as to the solubility of the various natural occurrences of the metal, and the physical and chemical characteristics of the material to be treated. The chief silver minerals are: the native metal and the sulphide, argentite; three species among the sulphi-arsenites and sulphi-antimonites, namely, proustite, or ruby silver; pyrrargyrite, or dark-red silver; and stephanite, or brittle silver; the bromide and chloro-bromide, bormyrite and emboleite; argentiferous tetrahedrite, containing sometimes as high as 30% silver as argentite; argentiferous galena, and blende containing silver as sulphide. The native silver is so slowly soluble in cyanide that practically no extraction from it can be obtained. Argentite is readily soluble, as likewise the chloride, the bromide, and the chloro-bromide. Proustite, pyrrargyrite, and stephanite are sparingly soluble in cyanide solution, but are readily soluble in a solution of mercuric potassic cyanide. The extraction of silver by cyanide from argentiferous galena, tetrahedrite, and blende is a problem yet to be solved. Taking these facts as a basis, in the absence of irremovable chemical interferences caused by the presence of base-metal compounds in the gangue, silver can be extracted from ores where it exists in soluble form, if the physical structure permits of solution-contact with the contained argentiferous compound. The application of the process then resolves itself into:

(1) Grinding to the necessary fineness for solution-contact; maintaining the strength and quantity of solution necessary; and giving a preliminary treatment or in adding chemicals other than cyanide to the mill solution.

(2) The advisability of classification of the milled ore into concentrate, sand, and slime, or into sand and slime before cyaniding.

In the case of gold-silver ores it is often advisable and sometimes necessary to amalgamate the coarse gold before concentration or cyaniding. The most obstructive chemical interference is due to the presence of oxide or carbonate of copper. It is claimed, and in one or two cases has been proved, that cuprous ammonium cyanide as a solvent has overcome this interference in the case of gold ores, but as yet this remedy has not been demonstrated in silver practice. Preliminary treatment with sulphuric acid for the removal of the copper salts has been successfully applied. I am of the opinion that the combination of the two remedies will solve most problems arising from copper interference.

The one other important interfering base-metal salt, namely, ferrous iron (when existing in a form not removable by preliminary treatment), is readily overcome in mill-solution by adding mercuric chloride. Ferric salts and ferrous sulphate interferences are readily overcome by preliminary treatment with lime. Manganese salts, when occurring in sufficient quantities to cause trouble (provided they do not exceed 3 or 4% Mn), can be precipitated during the process of treatment by adding to the solution an excess of calcium hydrate. Aluminum interferences are controlled by adding calcium hydroxide in excess. Soluble sulphides formed during treatment are neutralized by the use of lead acetate. In Mexican ores, we have not yet encountered base-metal salts, other than those mentioned, in sufficient quantity to cause trouble.

(To be Continued.)
STEAM SHOVEL IN COPPER MINING, ELY, NEVADA.

Written for the Mining and Scientific Press
By F. S. Phibby.

The steam shovel has been introduced in copper mining by the Nevada Consolidated Copper Co. at Ely, Nevada. Four shovels are in use, weighing 95 tons each, three working in overburden and one in ore. Shovels of 2½ cu. yd. capacity, now employed, will soon be replaced by shovels of 5 cu. yd. capacity. Recently one shovel, working 9 hours, handled 2800 cu. yd. Two shovels shown in the cut herewith are working in overburden. The man in the foreground stands on the rim of the ore pit, which is 22 ft. deep. The track shown is laid entirely on ore, by means of which the thickness of the overburden may be readily appreciated. It varies from 8 to 24 ft. Only a small amount of overburden has yet been removed; the entire amount to be cleared is nearly 3,000,000 cu. yd. and it is estimated to overlie not less than 15,000,000 tons of ore, having an average thickness of about 200 ft. On the left wall of the pit may be seen a drill in operation. Holes from 50 to 70 ft. are drilled for blasting. While the ore is exceedingly soft, and may be crushed in the hand when thoroughly disintegrated, shoveling is, nevertheless, materially aided by blasting. The overburden is greatly discolored by iron oxides, but only occasionally by copper. The line of demarcation between the ore and the overburden is as distinct as is that between a red and a white band. The cars shown are of 3½ cu. yd. capacity, but are to be replaced by larger ones. Those carrying the ore to the concentrator have a capacity of 50 tons, twenty making up a train. The cost for handling a ton of material does not exceed 55 cents.

DETERMINATION OF MOLYBDENUM IN WULFENITE.

By J. C. Evans.

*The following method has for its object the determination of molybdenum in wulfenite or other ores containing lead. The procedure consists in getting the ore into solution by the proper re-agents, the precipitation of the iron and lead as sulphides, the separation of molybdenum as sulphide, and its subsequent determination as lead molybdate, either gravimetrically or volumetrically. The method in detail is as follows:

From 0.5 gram to 5.0 grams of ore, depending on the amount of molybdenum contained, is digested in hydrochloric acid; nitric acid is afterward added and the treatment with hot aqua-regia continued until all soluble constituents of the ore are in solution; after one or two evaporations with nitric acid to expel all chlorides, the mixture is cooled, diluted with distilled water, and a slight excess of ammonia added. Ammonium sulphide is added, drop by drop, and when all the iron, lead, and other metals are converted into sulphides, a few c. c. excess are added, and, after stirring, the mixture is allowed to stand in a warm place until all the iron and lead sulphides have settled. It is then filtered, and washed with a solution containing a slight amount of ammonium sulphide. The precipitate is dissolved in a hot mixture of equal parts of nitric acid and bromine water, the iron and lead being reprecipitated by ammonia and ammonium sulphide to insure the removal of all the molybdenum. The combined filtrates, which show a deep brown color if much molybdenum be present, are slightly acidified with hydrochloric acid and a rapid stream of hydrogen sulphide gas is

*From the Western Chemist and Metallurgist, December 1907.
passed through the solution for a few moments. Theoretically, the addition of hydrochloric acid alone will precipitate all the molybdenum as sulphide, but I have found that the passage of hydrogen sulphide is necessary for complete precipitation. The molybdenum sulphide is filtered off and washed well with hot dilute hydrogen-sulphide water. The precipitate is then rinsed into a No. 2 beaker and a few c. c. of a hot mixture of nitric acid and bromine water are poured onto the paper, receiving the acid and washings in the beaker containing the bulk of the molybdenum sulphide.

The mixture is boiled with frequent additions of bromine to oxidize the free sulphur and to insure complete solution. From this point one of two courses may be pursued:

A. Gravimetric Method.—Any unoxidized sulphur is filtered off and, after careful washing, ammonia is added just to neutralization, using litmus paper as an indicator. A few drops of acetic acid are added, and then a slight excess of lead acetate, and the resulting lead molybdate, after stirring well and allowing to settle, is filtered through a tared Gooch crucible, or counterpoised filter paper as described by Blair (Chemical Analysis of Iron'), washed thoroughly with hot water and dried at 100° C. to constant weight. The weight of the lead molybdate multiplied by 0.2614 equals the weight of metallic molybdenum present, from which the percentage may be easily calculated.

B. Volumetric Method.—After the solution of the molybdenum sulphide, it is unnecessary to filter off any free sulphur present. The solution is almost neutralized with nitric acid, barely acidified with acetic acid, heated to boiling and, while hot, titrated with a standard solution of lead acetate, using a dilute solution of tannic acid on a spot-plate as an indicator. This is the well known method for molybdenum, and is the exact reverse of the Alexander titration method for lead. The solution at first gives an intense yellow color when a drop of it is added to a drop of dilute tannic acid on a spot-plate, and the addition of lead acetate is continued slowly until the yellow color just disappears. Knowing the standard strength of the lead acetate solution in terms of molybdenum, the percentage of molybdenum present in the ore is easily calculated. To prepare the solution of lead acetate, dissolve 15.70 grams of the c. p. Merck salt (it has been my experience that other brands frequently contain chloride) in dilute acetic acid, and make up to one litre. 25 c. c. of this solution is titrated against a standard solution of ammonium molybdate. The ammonium molybdate solution, having been standardized in terms of pure lead, shows the lead content of the lead acetate solution, and the lead factor multiplied by 0.4640 gives the molybdenum value. I have found this method more satisfactory than standardizing by means of molybdate acid, as it is very difficult to secure this re-agent free from impurities—especially molybdates.

Atlantic sea-water averages about 3.4% solid matter, of which 75% is sodium chloride.

UNDERGROUND AIR-COMPRESSIONS.

Discussing air-compression in mines before the Institution of Mining & Metallurgy, Fearnside Irvine stated that the small compressor would have this advantage over a large one, that it could be worked as a single-stage compressor with very nearly the same efficiency as a large compressor could be worked as a two-stage compressor. It would deliver its air at very little higher temperature, if any, than the larger compressor would do, and that air would be delivered underground close to the scene of operations; whereas the air from the large compressor would have to be conducted down the shaft and along the levels and through the pipe lines. The object of the electrically-driven underground-compressor was to get past that point, and to compress the air close up to where it was wanted, so as to have the pipe-lines as short as possible, and therefore open to supervision and able to be looked after.

There was another point in which the underground compressor had advantages, namely, that the generation of the compressed-air underground could be done at a much lower pressure than on the surface. If they took it that the surface compressor had to make air at 90 lb. in order to deliver it underground at 60 lb., they could easily put in an underground compressor near the work which could generate compressed air at 65 lb. and deliver it at 60 lb. through the short lengths of pipes, and they would therefore have the advantage of generating all their power at 65-lb. pressure instead of about 90 lb.

The saving of horse-power in that case would far more than compensate for any loss in transmission.

The underground compressor, taking electric power at practically the same potential as a compressor at the surface, had the advantage of saving first of all the capital-cost of the pipe-lines, next the loss in pressure due to those pipe-lines, and was thus able to generate compressed-air at a lower pressure, thereby saving power all around. Some small air-compressors working on single-stage compression turn out compressed-air at about 220 to 230° F.

Small compressors, with small cylinders whose cubical contents bear a very much smaller relation to the cooling surfaces of the cylinder walls and ends than is possible in larger sizes, are, especially when single-acting, very efficiently cooled; their piston speed in compression is also very low. Take, for instance, a single-acting cylinder with 9-in. stroke and 10-in. diam., 300 r. p. m., cooled in jacket and head, the cooling surface would be 361 sq. in., the cubical content 706 = 1 sq. in. cooling to 2 cubic content. In a cylinder 48 in. by 22 in. diam. the contents are 23,000, the cooling surface 3312 = 7/7.

Again, the speed of compression = at 75 r. p. m., 600 ft. per minute in the small compressor, 225; thus, the time in contact in the small cylinder = 2.6 times as long, and the surface is 31½ times as great = 974 times more cooling-effect. So far as efficiency is concerned, there is little difference between the two, and the small compressor working underground was a distinct advance upon the working of the large one on the surface.

which sane investors may stand in mining as well as in manufacturing ventures. That complete calmness of judgment and clarity of vision will ever dominate mine flotation, save in rare cases, is perhaps almost too much to expect. The glamour of the thing will exert its hypnotic effect, and the clever promoter will continue to lead his willing victims to the sacrifice. Even in England, stronghold of financial conservatism as it is, and long accustomed to comprehensive and rational presentation of the conditions of mining enterprises, the 'wild-cat' is not an unknown animal by any means. Only a few weeks ago the grandees of London were offering premiums on stock in a company for developing a rival of the Rand in—Gloucestershire! The function of the certified accountant is not to correct evils of policy, but to vouch for the accuracy of the figures presented in the balance-sheet. Questions of policy are determined by the directors of a company, and the one that shall prevail must depend upon custom growing out of a healthy public opinion.

American Shipping on the Pacific.

A RECENT ruling of the Inter-State Commerce Commission requires railroads to publish rates applying to the rail-haul upon through shipments from interior points to over-sea destinations. The order has created excitement in many quarters, which is justifiable if it really mean that the American flag would in consequence disappear from the Pacific Ocean. That would, so reasons the man in the street, strike a blow at all the Pacific ports, and every industry would have some participation in the disaster.

The sentimental desire to sustain American shipping, because it is American and carries the flag, is praiseworthy. This sentiment indeed ought to translate itself into motives of effective action. One or two lines of steamships on the Pacific, floating the Stars and Stripes and losing money, demonstrate either that conditions are unfavorable or that the people have not paid enough for their sentimental pleasure in the spectacle.

Analysis of the specific case presented seems to show that the order of the Inter-State Commerce Commission has practically nothing to do with the proposed withdrawal of the Pacific Mail Steamship line. That order only requires publicity, and publicity means, of course, that the rivals of the Pacific Mail would enjoy equal advantages in railroad rates, but they would still labor under the disadvantage of being unable to offer through bills of lading to consignors. This in itself would be an impediment of serious import. But under the conditions of secrecy shielding the rates which the Pacific Mail could quote, that company lost in the last fiscal year $428,817. This covers a portion of a year of phenomenal prosperity. Deficits of such magnitude would speedily determine the fate of the company. Evidently it is ready to yield to Japanese competition, regardless of any aid which the railroads might lend. In fact, if there were any hope of profit in the business, the steamship companies could readily be taken on lease by the railroads, and thus avoid the dilemma of publishing a rate which would benefit a rival; the railroad could practically absorb all the income from such business.

The Japanese are masters of the situation, and we can no more hope to withstand them than we may expect to dominate trans-Atlantic shipping, until our navigation laws have undergone radical reform. We do not operate ships as economically as foreigners. That is part of the difficulty. Neither do we any longer operate them better. That is a sort of union we may no more lay to our souls. If we did operate them better, we could drive the foreigner from the seas, as we did in the days of the famous, Baltimore clipper-ships. Illusions may as well be dropped. The report of the Merchant Marine Commission in 1905 showed, as one example, the annual salary and wage lists of the Pacific Mail steamship China, of 5060 tons register, to be $38,106, against $32,508 for the Japanese steamship America-Maru, of 6307 tons. This difference is not enough to prove an impenetrable obstacle to our ships. A very little advantage, such as through bills of lading would afford, easily could offset it. But the real trouble here on the Pacific, as also on the Atlantic, is the subsidy enjoyed by the foreigner. If we want our flag to float in the harbors of Tokio and Hongkong, we must invent some way of letting the American shipowner earn a living. We tried a mail-subsidy some years ago with the United States & Brazil Mail Steamship line, a line with beautiful ships which sailed empty, while its British rivals, with scruffy old boats, got the business. It is a painful memory, and somehow one cannot divest the mind of thoughts of the atrocity which is supposed to naturally follow any kind of parasitism. Why it does not work similarly with the foreigner is not readily answerable. At all events, our people do not like the thing called 'subsidy,' and perhaps we may never have it again. We could, of course, be rash enough to buy cheaper ships abroad, but we may as well confine our discussion to things that are possible. Free ships, after all the talk and tariff of so many decades, may be regarded as quite unthinkable. Discriminatory duties favoring goods imported in American bottoms once gave us the mastery of the carrying trade of the world. It would do so again, if any Administration had wit and diplomacy enough to disentangle us from the meshes of some foolish commercial treaties, so as to set the hands of Congress free to legislate.

Finally, each State has within its power the remission or reduction of taxes on American shipping, the abatement of port dues, and the regulation of other charges favoring vessels of domestic register. Many States have displayed enterprise enough to make some concessions of this nature, and such practical expression of sentimental joy in developing an American merchant marine has been responsible for some growth. But the favoring legislation has not been thorough enough. The State must extend its protection as far as it can, and the Federal Government must widen the opportunity by statutes as wise as those our forefathers enacted in the days when the Republic proved too weak to insist upon retaining its birthright.
Mining Claims on Forest Reserves.

LETTERS from officials of the United States Forest Service, which we are glad to publish in this issue, reveal that our statement on July 4 to the effect that titles could not be obtained to mill-sites on forest reserves is not true at the present time. According to the Use Book in force up to July 1, 1908, however, there was no instruction to officials relative to this matter. The new Use Book, issued on that date, from which our correspondents quote in refutation of our statement, had not reached us when our criticism was made. We had been convinced from previous conversation with leaders in the Forest Reserve movement that the policy of the Bureau was hostile to the patenting of mill-sites located subsequent to the creation of the Reserves, and it seems clear that the earlier Use Books contemplated the patenting of mineral land only.

The statement in Mr. Barrett's letter that "all (mineral) applications are examined by expert miners or geologists specially selected for the work" can have no general application. Mr. Hall, the Acting Forrester, does not claim this to be the fact, and the affirmation is in conflict with reports which come from other sources. Mr. Barrett was manifestly drawing broad inferences from his own jurisdiction. The appropriation by Congress is clearly inadequate for maintaining such a force of trained men as would be needed to facilitate reports of the character called for in substantiation of the validity of mining claims over the vast area covered by the national forests. The Forest Service, which properly inclines toward resistance of every influence that might endanger the conservation and improvement of the forests, must continue to see its cherished purposes thwarted to some extent by encroachments made under a strict interpretation of the mining law, as it applies to Government land in the West. Illegitimate straining of the law for purposes disconnected with mining in its true sense is unfortunately easy, and its prevention unfortunately difficult. It lies within the scope of the supervision exercised by the forest officers not only to determine whether the land contains enough mineral to warrant its disposal under patent in accordance with the mining laws, but to ascertain whether a claim is valid, and whether the locator has shown reasonable proof of the existence of valuable mineral sufficient to constitute a 'discovery' within the meaning of the statute.

It is clear to anyone familiar with the geology of mineral deposits that the application of such rules is quite impossible except in extraordinary cases, even with the aid of geologists and expert miners, until there shall be further restrictive legislation on which to base decisions. The examination of a placer deposit is a costly matter, and manifestly the forest officials cannot ordaincer ascertain whether a claim is capable of economical exploitation. The examination by panning of samples superficially taken, as recommended in the Use Book, would be utterly inconclusive. A 'vein' has been so variously defined by the courts that any claim containing the slightest mineralogical divergence from the character of the enclosing rocks would answer the requirement, and no man could positively affirm in the great majority of cases that it might not lead into deposits of commercial utility. The summary of decisions on this point by Judge Hawley (Cook v. Justice M. Co., 38 Fed. 106, 120) states the difficulty involved in a most explicit manner: "In some mining districts the veins, lodes, and ore deposits are so well and clearly defined as to avoid any questions being raised. In other localities the mineral is found in seams, narrow crevices, cracks, or fissures in the earth, the precise extent and character of which cannot be fully ascertained until expensive explorations are made, and the continuity of the ore and existence of the rock in place, bearing mineral, is established. It was never intended that the locator of a mining claim must determine all these facts before he would be entitled, under the law, to make a valid location."

The granting of mill-sites presupposes the existence of grist to bring to mill. The advocates of national forests in the beginning desired a separate mining law, applicable to the Reserves, involving a return to the lease-hold system obtaining before the law of 1866. This fortunately failed of accomplishment. The principle of fee-simple ownership has become too firmly fixed in the habits and esteem of the people to be abandoned. But if the Forest Service is purposing to lessen the restrictions upon the acquisition of rights under the mining law, and to admit the application of that law on the same terms as upon other portions of the national domain, the way is being opened to operations which will necessarily be injurious to the forests. The removal of restrictions to the patenting of mill-sites is but one step in the inevitable recognition of the full liberty that may be claimed under the mining statutes. The development of mineral resources is necessary for national progress, but likewise is the preservation of the forests, in the vital need which exists for conserving timber and permanent water-supply. The spirit underlying legislation is, or should be, the attainment of the greatest good for the greatest number. There have been few movements in recent years that so completely gave expression to this utilitarian spirit as the national forest legislation. The depression caused throughout the California 'gold belt' every year from scarcity of water is an example of the need of such administration of the forests as will promote their development. The good which would follow from an extension of the working season of the mines along this zone would require phenomenal mineral developments in the Reserves to offer compensation for any further injury which might result to the forests on the watersheds. The chief danger, however, is not from legitimate mining, but from fraudulent application of the mining law to attain other purposes. It is evident that restriction by regulations, involving interpretation of the statutes by the Forest Service, is destined to fail. In that case remedial legislation would seem to be necesitated. Efforts to construe the existing law must inevitably lead in time to a contest which will bring forth a court decision that will pull down the barriers the Forest Service has been trying to erect.
Personal.

F. W. Oldfield is at Bannock, Montana.

S. F. Shaw is examining mines near Jimenez, Chih., Mexico.

Clarence Hamshaw, of New York, is at Fairbanks, Alaska.

H. C. Perring is on the staff of the Yukon Gold Co., at Dawson.

F. L. Ransome, of the U. S. Geological Survey staff, is at Rhyolite.

Frank H. Probert, of Los Angeles, was in San Francisco this week.

N. S. Samwell is examining placer mines in the Salween district, Burma.

George S. Drinkley, of Los Angeles, was in San Francisco this week.

J. R. Finlay, of New York, has been in the Joplin district of Missouri.

Romer T. Hill has returned to New York from a professional trip to Mexico.

James F. Kemp, of New York, is making a tour of the western mining camps.

G. T. Coffey is hydraulic engineer for the Yukon Gold Co., at Dawson, Yukon.

R. H. Campbell, of San Francisco, was at Dawson lately and is now at Fairbanks.

Bertram Hunt has returned to San Francisco from Tuolumne county, California.

E. H. Messiter is now with the Robins Conveying Belt Co., at Passaic, New Jersey.

Ellsworth Daggett was in San Francisco this week and has gone to British Columbia.

G. L. Eady has been appointed assayer at the plant of the Peyton Chemical Co., at Martinez.

R. H. Tol, of Denver, is examining mines in the La Plata Mountains, in southwestern Colorado.

Robert Hanley has been appointed superintendent of the Mammoth mine, at Kennett, California.

E. E. McCarthy is superintendent of the dredging operations of the Yukon Gold Co., at Dawson.

Joseph W. Teale has been taken into the firm of Bainbridge, Seymour & Co., London, as a partner.

Oscar H. Hershey has returned from French Gulch, Shasta county, where he has been examining mines.

G. A. R. Levinson is advisory mining engineer to the North American Trading & Transportation Co., of Dawson, in the Yukon Territory.

S. Herbert Cox has retired from the firm of Bainbridge, Seymour & Co., London, to accept the Chair of Mining at the Royal School of Mines.

James E. Chapman, formerly at the Dorelos property of the Guggenheims, is now at the Bonanza unit of the same interests, at Bonanza, Zacatecas, Mexico.

W. J. Adams, of the firm of Brandham & Adams, mining engineers of San Francisco, has withdrawn from the firm, and his address is now 237 Sansome street.

M. W. Summerhayes has recently returned from a two weeks’ visit to the property of the Compania Minera Juarez, near Cabeca, Sonora, where he was investigating the presentcyanidation and reduction operations, with a view to increasing the capacity.

Dividends.

On August 4 the Bunker Hill & Sullivan Mining & Concentrating Co. paid dividend No. 131, of $75,000. This makes the amount of dividends paid since January 1, $555,000, and the total to date $10,371,000.

BY COURTESY OF W. C. RAILEN, 35 BUSH ST.
General Mining News.

ALASKA.

(Special Correspondence).—An unusually dry season in the neighborhood of Nome is greatly retarding placer mining, especially among the smaller operators. The immense ditch systems, now completed, have exhausted the small streams near the coast line. The Wild Goose, the Pioneer, and other big companies are discharging hundreds of men owing to shortage of water. This, and the fact that the placer mining is almost entirely controlled by the large companies, has caused almost a stagnation of business at Nome. A German steam pump stationed for Anadyr, Siberia, on July 1, and took with her a number of American miners. The Governor of Siberia was recently in Nome and gave considerable encouragement to prospectors. All ground, except that of the N. E. Siberian Co.'s concessions, may be located and worked on 10% royalty.—A drill has recently been completed at Nome which is able to travel under its own power over the steepest tundra marshes. The tires of the wheels are four feet wide.—Two big hydraulic lifts have been installed by the Fairhavwen Water Co. on the Innachuck river.—About 600 miners have gone to the Kougakor region since June 1, due to the recent strikes on the Macklin and other creeks of that district.

The Universe Ditch Co. has begun hydraulicering on Glacier creek. A clean-up on the alluvium of two days' run, was made on July 5 which netted $34,000. The property is a valuable one and has been worked by a New York company, which cleared $30,000 during ten months operations, and by the Shannon Copper Co.—The Tombstone Con. Co. is preparing to resume work on the Lucky Cuss property, which has been idle since last November, when the entire plant was destroyed by fire. The plant of the Toughtnut property of the Consolidated is being moved to the Lucky Cuss and will be erected and ready to use within 30 days.

MARICOPA COUNTY.

C. T. Wolcott, of Colorado, has been in Wickenburg recently looking over the situation with a view to deciding on the location of a smelting plant.—The Chile mill of the Monarch M. & S. Co., nine miles southeast of Wickenburg, has started again. Fire destroyed the plant last year and thus retarded the operations of the company. The shaft is 150 ft. deep and has been in ore for the last 100 ft., which would indicate that the vein is at least 25 ft. wide.

PIMA COUNTY.

It is probable that the Helvetia Copper M. & S. Co. will soon blow-in its 150-ton furnace at its smelter at Helvetia. There are 2000 tons of ore on the dumps at the smelter and immense quantities blocked out in the mines. One hundred men are now at work.

TAYAPA COUNTY.

(Special Correspondence).—The Emporia Con. M. Co. has been recently incorporated to take over the Emporia property in the Groom Creek district. A new two-compartment shaft has been started and a head-frame erected. The shaft is 50 ft. deep, and has cut two veins, one lying against the foot-wall, which is 4 ft. thick and assays $12 to $14 gold per ton, the other is against the hanging wall, and is 8 ft. thick, assaying nearly $8. It is probable that a 10-stamp mill will be erected and possibly two Huntingtons mills added later. The mill-site is on Wolf creek, a distance of half a mile from the shaft, and will be connected with the mine by a tramway. A reservoir near the mill-site is now under construction. The Company is working 12 men in one shift. H. H. Keays is superintendent.—The various properties of the Arizona Smelting Co., bankrupt, consisting of mines, stocks, securities, and a smelter at Humboldt were offered for sale at Prescott on July 25. The minimum demand was $175,000, and the appraised value of the properties. No bids were received and the announcement was made that private bids would be received at the law offices of Norris & Ross, said bids to be subject to the confirmation of the Court.

Prescott, August 1.

CALIFORNIA.

BUTTE COUNTY.

A forest fire last week destroyed the mill of the Cortez Mining Co. and the flumes on the property of J. G. Alm, both on McCabes creek, southeast of Enterprise.

ELDORADO COUNTY.

Another shipment of machinery for the Gold Hill mine, in Bear Creek district, arrived in Placerville last week.—The Garden Valley Gold Mining Co., which recently purchased the Hume property, has begun development work on the claim, which has been named the Old Lady's mine. H. H. Hicks of Grass Valley is in charge of the mine.—It is reported on good authority that the Zentrafta mine, in the western part of the county, which has long been closed on account of litigation, is soon to be re-opened.—The mill of the Ritter mine, near Eldorado, has started again, and is treating ore from the 400-ft. level. The mill is on Murray creek and the cars are lowered on a 700-ft. incline tramway to the ore-bins.

NEVADA COUNTY.

(Special Correspondence).—The New York-Grass Valley mine has been compelled to suspend operations owing to the turning off of water by the Blue Point M. Co. It is reported that the matter will be taken into the courts.—The work has been resumed at the Normandie, and plans have been made to enlarge the Blue Point ditches; 150 men will be employed. The ditches are owned by the New Blue Point M. Co., and supplies water for the Blue Point mine at Smartsville. Work on the mine will be started this fall, according to present plans.—The sinking has been resumed at Mida.—The South Wha Water Co. has announced that it may be forced to deprive the local mines of water within 30 days. The company is using its reserve supply, and the continued hot weather, together with the absence of rain, renders the water situation serious.—It is reported that the Ironclad mine will shortly be re-opened and work pushed on a large scale. A new pump, compressor, and other machinery will be installed. A 20-stamp mill is under consideration for the Normandie group of claims, at Deadman's Flat, has been bonded by Santa Barbara and Eastern people. The consideration is said to be nearly $100,000. The Normandie shaft will be unwatered and sunk deeper and a new shaft will be started on the Dulmaine claim. Harry S. Abbott is general manager.—The Oustonah mine has reverted to the owners, following the failure of the Hayes brothers to exercise their option on the property. The owners will immediately resume operations, with Frank S. Morgan as superintendent.—San Francisco people have bonded the Dower mine, on Canyon creek, and are arranging to commence work. The property lies near the Marcotte.—The adit at the Kohler mine is to be pushed ahead with a large force of men. A new compressor will be installed, and Frank McPherson is superintendent.—The English syndicate has secured an extension of their bond on the Champion
and Delhi mines until September 1. H. G. Torrence and associates are on their way to Nevada City from London to look after the interests of the firm. The Giant King mines have passed into full possession of the Washington M. & M. Co. The company will erect an electric power plant to operate the properties. It is planned to install considerable machinery, including a 20-stamp mill.

The Lecompton shaft has been unwatered to the 300-ft. level. A 12-in. Cornish pump is employed. As soon as the 500-ft. level has been reached active developments will be commenced.

GRASS VALLEY, August 3.

PLACER COUNTY.

The Parmalee mine is being put in condition to be worked. Compressors and other machinery are being put in place.—W. A. Fletcher will install an electric plant on the North Fork of the Middle Fork, to run the mill at the Homestake mine, at Last Chance; the Paragon, at Bath, and the old Dardanelles, near Forest Hill. He has put more men at work at the Dardanelles, and will drive the Black Hawk adit ahead. The old tunnel run by Chapman is in 600 ft., and he expects to run 150 ft. farther to strike the channel.—Tom Harris has located on a big vein just across Bear river from Landers. The vein carries molybdenite, antimony, and galena. A compressor is being installed at the Homestake.

SIERRA COUNTY.

The United States & British Columbia Mining Co., of Boston, has taken an option on the Wintering and the Os-good groups of claims on Russian creek. By the terms of the agreement the purchasers pay $3,000 each and agree to put 12 men at work immediately. A total of $100,000 will be paid for a four-fifths interest, the owner retaining one-fifth.

TUOLUMNE COUNTY.

Ten stamps will be added to Driesam mill, and the shaft deepened 250 ft., making a total of 650. Twenty men are employed. The Golden Eagle mine, near Confidence, has been bonded by W. H. Swan and H. C. Parry, of Oakland, who will start development at once.—A cross-cut from the shaft at the 500-ft. level in the Omega has reached the vein. It is reported that the ore has been penetrated 20 ft., and no signs of the hanging wall.

COLORADO.

CLEAR CREEK COUNTY.

(Special Correspondence.—Butts & Co., leasing on the Astor, broke into the old engine-room this week. It was always supposed that the room was on the 80-ft. level, but it now develops that it is on the 225-ft. level. A streak of ore had been followed for 70 ft., but where the old workings were struck the ore disappeared, being found 2 ft. to the west and 10 ft. below where it was supposed. The strike made in years on Democrac Mtn. There remains a vast area of virgin territory to be explored.—Work is to be resumed upon the Rover property, on Griffith Mtn. The property is owned by C. D. Turpin, of Rochester, N. Y., who is now in camp. The Rover is an extension of both the Astor and the Comet.—A deal has practically been closed whereby a group of claims and the Evergreen holdings on Republican Mtn. are to be consolidated. Work has already been put under way with W. H. Maxton in charge. It is the purpose of the management to extend the Lebanon adit several hundred feet, as a series of 39 veins is controlled, none of which have been developed below a depth of 200 ft.—The bond of $19,000 on the Gambetta group of claims, Republican Mtn., was lifted this week. A force of men was at once put to work in breaking ore and shipments will be started next week. A wagon road is being built to the portal of the adit. The drift on the Gambetta vein has been run for 180 ft. and a streak of $100 ore is exposed that is from 12 to 18 in. wide.—The Raymond adit is now in 550 ft. a lode having been intersected. The extent of the discovery is not yet known, as hanging wall has not been reached. Driving and stoping are under way upon the Paris vein, which was cut 500 ft. from the adit entrance, and a considerable amount of mined ore is worth about $35 per ton in silver and lead. Joseph Raymond, of Georgetown, is manager.—J. McAdams has taken a lease on the Allunde and is carrying on work through the Ocean Wave level. A winze is being sunk and a streak of ore is being followed that is from 6 to 8 in. wide and assays 425 oz. silver per ton.—Active work is now under way upon the Mollee Bawn, on Silver Mtn. The adit is being advanced and an immense hoddy is exposed in the breast. This property is to be equipped with a small mill. H. C. Newton, of Denver, is in charge.—The Marshall-Russell adit has now been driven for 150 ft., progress being made at the rate of 6½ ft. per day. Within 175 ft. the Neef vein will be intersected.—A rich strike is reported from the stoping made on the Cram vein through the Doric adit workings. The strike is from 8 to 10 in. wide and the ore shows some free gold. Assays show from 8 to 12 oz. gold per ton.—Shipments of concentrating ore from the Columbia mine, at Empire, are being made to the Newton mill, at Idaho Springs. Graham & Schlegel, operating under bond and lease, have a body of ore that is 3 ft. wide and worth from $12 to $16 per ton.—The Seemann tunnel, on south river, is now being advanced for 215 ft. A large power plant is being constructed, the machinery being on the ground. The Seemann tunnel is to be driven under James peak and will be used both for mining and transportation purposes. Power is to be sold throughout the Alice-Yankee districts. Henry I. Seemann of Denver is manager.

GEORGETOWN, August 1.

OLDFIELD COUNTY.

The Quartz Mill mine has been purchased by a company of Colorado and Iowa people, headed by O. J. Duffield, of Denver. The property is in Leavenworth gulch and comprises three claims. The main shaft, on the Quartz Mill claim, is 300 ft. deep. A good plant of machinery and buildings are already on the property and development will be started at once. J. H. Bawden, of Arvada, will have charge of the operations.—A good strike was recently made at the 300-ft. level of the Senator mine, below Black Hawk. A sample from a four-inch streak assayed $135 per ton in gold and silver.

LAKE COUNTY.

Christenson Bros., who are working the Pioneer adit near Granite, have opened a streak of ore carrying 8 oz. Shipments will be made to the Monday mill.—It is probable that a spur will be built from the Denver & Rio Grande to the Valley shaft, on Little Ellen hill, after which the rate of shipments will be greatly increased.

OURAY COUNTY.

The contract for the steel smelter-building at Ironon has been let to the Taylor Engineering Co., of New York. The Mone-Baltic Co. will treat not only the ore from its own mine, but will accept custom work. It is hoped the plant will be blown in early this fall.—Herzinger & Sigfrid have secured options on the old Powell smelter and on several claims in the Gold Belt. The outcome of the contract depends upon the report of engineers who have examined the properties. If consummated the project means a revival of mining interests among Ouray.—The shifts on the Torpedo-Eclipse adit will be doubled as soon as the new boarding and bunk houses can be finished. The boarding house is now complete except for the modern plumbing system which is to be put in as soon as the project is ready. The lumber for the mill has been ordered from the Illawalla smelter. The Camp Bird Extension Co., owning 35 claims and several mill-sites in the Sneffels district, was incorporated last week under the name of the Amity Gold Mining Co., with a capitalisation of $2,000,000, one-half of which is in the treasury. Extensive development work will begin on the properties immediately. G. L. Wright, of Ouray, is interested in the new corporation.
SAN JUAN COUNTY.

The financial affairs of the Gold King Mining Co., have been adjusted and the application for the appointment of a receiver has been withdrawn. A number of men have started work and repairs to the tramway and buildings will soon be started.—The Iron Magnet, near Chat-

tanooga, owned by J. R. Curry, is being worked again this season. Some rich pockets have recently been uncovered and it is possible that a good mine may yet result. Mr. Curry is blind and the operations are directed by his wife.

TELLER COUNTY.

Negotiations are now pending and will be concluded within a few days for the resumption of operations on the Copper Mtn. cyanide works owned by the Brockton-Alaska Gold Mining Co. Bull and associates, who operated on a large body of low-grade ore some time ago on the Flourine property, owned by the Montrose Mining & Milling Co., will operate the mill which has been idle for over two years.—McLeod Bros., have secured a lease on the No. 2 shaft of the Anaconda holdings of the Mary McKinney Co., on Gold hill and will start operations immediately. A steam-boat is now being installed.—The Taylor & Brunton sampler, at Goldfield, has been purchased by George E. Copeland and associates. Mr. Copeland has been manager of the plant since 1903 and as part owner will continue in that capacity.—The Mary McKinney Gold Mining Co., paid, last week, the first dividend in over a year. This distribution is at the rate of one cent per share and makes a total of $2,000 to the share-holders. —The Anaconda Electric Co., on the No. 2 shaft, of the Anaconda holdings of the Mary McKinney Co., has been organized and a group, including Mr. Johnson, the manager, has just been purchased by Mr. Copeland and associates. Mr. Copeland has been manager of the plant since 1903 and as part owner will continue in that capacity. The Mary McKinney Gold Mining Co., paid, last week, the first dividend in over a year. This distribution is at the rate of one cent per share and makes a total of $2,000 to the share-holders. The Anaconda Electric Co., on the No. 2 shaft, of the Anaconda holdings of the Mary McKinney Co., has been organized and a group, including Mr. Johnson, the manager, has just been purchased by Mr. Copeland and associates. Mr. Copeland has been manager of the plant since 1903 and as part owner will continue in that capacity.

IDAHO.

IDAHO COUNTY.

The shaft at the Buster mine has reached a depth of 300 ft. A cross-cut will be started at the 400-ft. point and it is hoped to reach the vein by September 1.—Richard Klessattle has made the final payment on the Diamond group, near Dixie. It is said that active development will be carried on all summer and next winter and that a 20-stamp mill will probably be erected.

OWYHEE COUNTY.

The Banner mill, at Silver City, was formally opened recently. The equipment includes a 4-stamp battery of the Salmon Falls type, Blake classifier, Charbonneau tables, Johnson tables, amalgamating pans, and other accessories. The mill is operated by electric power from the plant at Swan Falls, 30 miles distant, on Snake river, which is transmitted at a pressure of 22,000 volts.—The Silver City M. & M. Co. has been incorporated to work the Abel Berg property, in Long gulch, on the eastern side of Florida Mtn. The group embraces four claims and a mill-site. J. E. Masters has been appointed manager.

SHOSHONE COUNTY.

(Special Correspondence).—The principal item of interest during the past week in the Cuer d’Alene was the announcement that the Greenough Bros., have purchased the control of the Panhandle smelter on Lake Ponderay, together with large areas of iron deposits. It has been known for a long time that the Greenoughs have been anxious to place the Snowstorm mine, the big copper producer, on an entirely independent basis, and it was doubtless with this object in view that the purchase of the Panhandle smelter was made. The buildings for the roasters and machinery will soon be completed. The blast-furnace is being forwarded to the property and is all but ready for installation. It is expected that the plant will be in full operation within a month. Of the 30,000 tons of ore to be smelted will come from the Montana mines and the plant will handle about 250 tons of ore per day, enough having been guaranteed to keep the plant in steady operation. — A shipment of 25 tons of ore has been made from the prop-

cery of the Grizzly Copper Co., at Osburn. This is the first shipment from the property and is of considerable signi-

ficance to the large number of prospects working in that district. The ore shipped averaged about $30 per ton in copper, silver, and gold. It has been stopped from the sides of the shaft which was sunk on the vein, and the present indications for a mine are excellent. As the result of a general appeal to the county commissioners the assessment on the big dividend paying mines of the district has been lowered about $15,000, approrriated as follows:

<table>
<thead>
<tr>
<th>Company</th>
<th>Assessment Amount</th>
</tr>
</thead>
<tbody>
<tr>
<td>Federal M. &amp; S. Co</td>
<td>$13,500</td>

A rich strike of lead-silver ore is reported to have been made in the shaft of the Full Moon property. The shaft has been sunk 50 ft., and practically the whole face is in carbonate ore carrying stringers of a very high quality. The management has decided to run a long adit to get under the orebody. A large equipment of machinery will be installed at once. The adit will be 800 ft. long and will give a depth of 400 ft. under the shaft. The Stanley mine, which has been closed since June, is to be equipped with a reduction plant this fall and the option on the New Jersey mill, which expired July 1, is to be given up. It is stated by Mr. Merk, the manager of the property, that the mine closed down more on account of the scarcity of men than anything else. The Cornish type of operation of the mill at half-capacity too expensive, and the ex-

iment was sufficient to convince the management that on account of the antiquity in the ore, amalgamation was not the best process available. The mine will not be started again until its own mill has been completed. This plant is expected to be ready in about 60 days and the Company is now waiting for the settlement of the litigation filed by Hercules, by which they seek to restrain that Company from dumping its tailing on the patented land of the Stan-
ley above the mill-site. The new plant will consist of tables, rolls, jigs, and will have a capacity of from 40 to 50 tons per day.—The Schulz Mining Co. has been incorpo-

rated at Wallace and will operate a group of seven claims adjoining the Wonderful and the Bullion. The Temple mine is reported to have struck galena in a shaft which is being sunk to determine the position of the vein. An adit will be run at lower depth to tap the orebody when its position is ascertained.—The capacity of the famous Bunker Hill & Sullivan mill at Wardner is to be doubled. Work has been commenced on the erection of a 100-ton plant, and it is expected that the first unit of 50 tons will be completed by the end of November or the begin-
ning of December. All the grading has been done with the aid of a steam-shovel, and it is expected that the improvements will cost in the neighborhood of $80,000. The mill will be situated about 400 ft. south of the present mill and 700 ft. from the portal of what is known as the Kellogg tunnel on the O. & R. & N. railroad track. The foundation for the mill will be completed this week. Most of the equipment has already been ordered from the East and includes crushing rolls, jigs, classifiers, Willey tables, and Card concentra-

ting tables. Electric power for the mill will be furnished by the Washington Water Power Co., of Spokane. The output from the mine will be handled by the new mill, and work will be commenced at once to remodel, overhaul, and bring the old mill up to date. New machinery will be installed, and when this is finished both the mills will have a capacity of 2000 tons per day. Originally the old mill was supposed to have a capacity of 1000 tons per day, but the Company has been crowding it with 1100 tons in a satisfactory manner. Only one shift of eight hours is worked in the mine and this is enough to keep the mill running 14 hours 55 minutes per day. The new mill will be located on the mine, mill, and on construction. The ore now being taken out assays 14% lead and 4 oz. silver. There is practically no zinc in the product.

Wallace, August 3.
KANSAS.

CHEROKEE COUNTY.

(Special Correspondence).—A new producer was this week added to the Galena field. The development work has been completed by the Hartford Co., which has been doing extensive prospecting the past year. A number of shafts were sunk and sufficient driving done to open up the orebody necessary to supply a 300-ton mill, which has just been completed. Active operations will be begun at once and will add materially to the output from the Galena camp. A second shaft is being sunk near the mill, and one of the richest mines opened in this camp is the Rains, Sapp & Moore property west of the Century hotel. As development progresses the ore increases in richness. This finding disproves the belief that all the ore had been worked out in this city, as this property is situated in the very heart of Galena.

In the Baxter Springs camp ten plants are either producing or doing development work. The Mission mine, after a brief shut-down, is again producing and getting ready to begin the construction of the new mill. A new shaft will be sunk.—The Hawleye mine has been closed down temporarily to install a large six-inch Scranton pump. This will make a duplicate pumping system. Other improvements and repairs were made during the shut-down.

The Chief-Quapaw mine is again working on a new shaft, off the Julian Stafford "forty." Driving is being done preparatory to building a new mill the latter part of the summer.

Galena, July 25.

NEVADA.

ESMERALDA COUNTY.

The flow of water which impeded operations in the Mitchell & Fairfield lease on blocks 7 and 12 of Combination, has been reduced to small proportions and sinking is proceeding rapidly. The shaft is now down 250 ft. and will go to the 500-ft. point unless payable ore is found before that level is reached.—The old Wavery lease on the C. O. D. has passed into the hands of Heslip & Jeffries. They will begin work some time next week. Several veins of low-grade ore were uncovered by the former leaseholders. The shaft is down 300 ft. and the property is equipped with a fine plant of machinery.—It is reported that the Pictolus mines, east of Launig, have been sold to Eastern people for $56,000, and that big machinery is to be installed at once.—The old Queen lease, on the Florence ground, will be started again, and will be known as the Zinn Florence. There is now a 400-ft. shaft on the lease, equipped with a hoist, and prospects for a good production are bright.—The contract for building the railroad to Rawhide has been transferred to E. W. King. Fifteen of the 25.6 miles have been graded and are ready for the rail laying. The water company will have its supply at the camp within 60 days. Water will be supplied at $.25c per gallon.—The Goldfield Syndicate Mining Co., which owns a one-half interest in the Rogers Syndicate lease, has purchased the Nevada Rockland mine, near Fine Grove. The property was equipped with a mill by Eastern people who worked it last year on a bond. —The Gris Hill mine, at Rawhide, shipped a carload of ore-screenings that averaged $440 per ton. Two more carloads of similar ore are ready for shipment.—The mines of Goldfield produced during the week ending August 1 a total of 1772 tons, estimated to be worth $221,860. During the same period the Tonopah mines produced 5065 tons, of an estimated value of $156,175.

HUMBOLDT COUNTY.

Machinery and equipment have been recently purchased to increase the operations on the Vons & Bulson lease on the Rosebud. This lease is working two shafts on the east and west drifts of the 100-ft. level, and good orebodies have been developed.—The Nevada Humboldt Electric Power & Light Co. has been incorporated. The capitalization is $1,600,000 shares. Power will be derived from Clear creek, in Humboldt county. It is the intention of the Company to supply power to all the camps of the Seven Troughs district. I. H. Rogers is president of the Company. The water-right will develop about 1500 hp, at the lowest stage of the stream.—The Sheba mine, near Mill City, which has been closed down for a year, is soon to be started up again with a large force of men.

UYE COUNTY.

J. C. McCormack and associates have purchased the Clifford group, nine miles from Stone Cabin. Water rights and a mill-site are included. It is reported that assays run as high as $4316 in gold and silver. The consideration is not stated. —A body of ore has been uncovered at the 68 lease on Ladd Mtn. The ore was found in a cross-cut which is being driven to connect with the bottom of the winzes.—It is reported that the Rose Gold M. & M. Co., operating a mile and a half south of Curry's well, will put in a mill and machine-drills.—The miners of Rhyolite have decided by popular vote to accept the Tonopah scale of wages.

LINCOLN COUNTY.

The Philadelphia-Searlelight, after being closed down less than a week, has resumed. The close-down was caused by a misunderstanding as to the securing of a loan.—The new air-compressor that has recently been installed at the Mandha property, at Pioche, is now in operation, and T. J. Osborne says that the first test was most satisfactory. Shipments from this property are scheduled to begin in the near future.—The Goldfield & Searchlight Mining Co., recently incorporated, has shipped supplies to its property near Pioche, and will push operations.—A new pump and hoist are being installed at the Shannon Bells M. Co.'s property at Eldorado canyon. As soon as this machinery is in place the main shaft will be sunk as rapidly as possible. A cross-cut is being started from the 700-ft. level, which is at the water-level, to tap the main vein. A new shaft is being started on the vein, which gives good assays.—The Pioche-Mohawk is asking for bids for sinking a 125-ft. shaft on one of its claims. A Buffalo whim and other supplies are on the ground and will be used as soon as the contract is started.—The Baltimore started sinking on its 500-ft. shaft the first of this week. New holding machinery has been erected.—The Nevada-Utah Mines & Smelting Co. have resumed the schedule of two trains per day on their Pioche-Jack Rabbit run. It is now necessary to supply water for two sets of boilers recently put in at the Onondago mine, and the shipments of ore from the Day mine commenced this week.

NEW MEXICO.

The Pan American Federal S. & R. Co. will build a 100-ton smelter at Socorro. The citizens of the town have subscribed for $10,000 of the total cost of the plant, and have also furnished the site on which it is to be built. It is claimed that the construction will be started by August 15. The same company is building three other smelters; one at Lordsburg, one at Van Horn, Texas, and a third at Nogales, Arizona.—The Copper Gulf Mining Co., and the Comanche Mining & Smelting Co., have been merged into one company having a capital stock of $2,000,000. The new company will probably be called the Copper Gulf Mining Co., and will have 4000 acres of mineral ground in the vicinity of Silver City, mostly developed, including the famous Pinos Altos mines, formerly opened by Senator Hearst. The Comanche has a concentrator and smelter at Silver City and a railroad from there to Pinos Altos. A strike of rich ore is reported from the Mamie claim at Oro Grande. The whole shaft is in ore and assays run from $29 to $715.

UTAH.

BEAVER COUNTY.

It is reported that the Majestic Mines Co. will resume work at once at its Harrington H Hickory mines. This property is one of the most valuable holdings of the Majestic, and has a record of a large production.

JUAB COUNTY.

The Victoria mine at Tintic has resumed the shipment of ore and is now sending out two cars per week. This will soon be materially increased when the new smelter can handle a large tonnage.—Following the policy which has been in vogue at several of the older mines of the Tintic
mining district for some time, the management of the Yankee Consolidated has decided to try the leasing system, and at least a half dozen leases will soon be in operation on the several upper levels of the property. In the meantime the company will continue the development and extraction of ore from new territory. The claims of the old Martha Washington Mining Co., near Silver City, have passed into the hands of Jesse Knight and will become a part of the Dragon Iron Co., the corporation which was recently formed to take over the old Dragon Iron mine and other adjoining territory. The dissolution of the Juab Mining Co. and the Plutus Co. Mining Co., the former with a capital stock of $250,000 and the latter with a capital stock of $300,000, will mean the formation of a new company which will take over the groups of claims of these two Companies and some other adjoining territory. The Juab and the Plutus are old companies under the control of Jesse Knight. The first distributes among its shareholders assets valued at $13,800, and the latter $30,000. The ground owned by the Companies is upon the ridge to the southeast of Kureika. —The burning out of three generators at the plant of

the Utah County Power Co. left the Knight mines without power last week and resulted in the temporary closing down of the Crown Point and the suspension of work in the new shaft of the Sioux Con. The damage has been repaired and work is now going on as usual. —A rumor has been in circulation here to the effect that the Crown Point Co. will install machinery and be independent of the Colorado.

SALT LAKE COUNTY.

The United States, R. & M. Co. is operating its lead smelter at Bingham Junction, on an oxidized charge in two furnaces, and a third is likely to go in by the end of this week. It is expected that three more will be operating on sulphide ore by the middle of August. The plant is equipped with six lead furnaces, each of a capacity for 300 tons of ore per day.

SUMMIT COUNTY.

The zinc concentrating mill of the Grasselli Chemical Co., at Park City, has been closed for the purpose of building an addition to the plant and providing equipment to treat a larger tonnage. The company has a contract with the Daly Judge Mining Co., the latter having between 12,000 and 15,000 tons of zinc middling available for separation. —The ore shipments from the Park City mines for the week ending August 1 were as follows: Daly Judge, 966,000; Silver King, 1,716,000; Daly West, 1,000,000; Hayes lease, 25,000. Total, 3,797,000 tons.

WASHINGTON.

FERRY COUNTY.

(Special Correspondence).—W. M. Crummer and Nels Erickson, who are leasing the insurgent mine, at Republic, are driving on a vein on the lower adit level which has recently been intersected by a cross-cut. It is 12 ft. wide at that point and appearances indicate a pay-shoot near at hand. —Richard Mulroy, lessee of the Republic mine, has another carload of ore ready for shipment.

Republic, August 3.

STEVENS COUNTY.

(Special Correspondence).—In the Last Chance mine, on Deep creek, in the Northport district, at a depth of 70 ft. a 2-ft. vein of high-grade galena has been struck. —At the Jay Gould mine, in the Chewelah district, five men are employed shanking below the 100 ft. level. The shaft will be sunk to the 200-ft. level. A blind lead, having a width of about 25 ft., was struck on the 150-ft. level, the ore from which assays $9 per ton. —A 6-ft. vein of high-grade copper ore has been discovered on Granite Mtn., east of Box canyon, in Metaline district.

Republic, August 3.

CANADA.

BRITISH COLUMBIA.

A serious forest-fire has been raging in Kootenay since August 1. The town of Fernie is completely devastated, with 20 lives lost and $5,000,000 worth of property destroyed. Michel will probably be wiped out, and Hosmer, Sparwood, and Coal Creek are seriously damaged. The total loss of lives will probably be at least 40, and fully 7,000 people are homeless. The burned area stretches for 50 miles along the Canadian Pacific railroad, and while it is but one mile wide in some places, in others it is 10 miles. The loss to standing timber is estimated at $2,000,000. It is rumored that the origin of fire at Fernie was of incendiary nature. —The Diamond-Texas, near Greenwood, which has been shut down for some time, has resumed again. —It is stated that the Prince Henry, one of the best high-grade properties in Greenwood camp, is expected to resume operations shortly. A drill is at present under way for the purpose of financing the work. —Shipments from Boundary mines for the week ending July 25 amounted to 38,113 tons. This is the biggest weekly tonnage in the history of the Boundary, with one exception. In the third week of September, 1907, the shipments were 41,734 tons. The next largest was 37,111, in July, 1907. —Poised on the edge of one shipped from and crushed at the mines of Rossland for the week ending July 25: Centre Star, 3450; Le Roi, 1500; Le Roi No. 2, 525; Sunset, 25, Total, 5500 tons. Total for year to date, 162,097 tons. The district shipments for the past week were: Boundary, 38,107; Rossland, 5500; Slocan Kootenay, 2923 tons. Total for the week, 45,520 tons. —The Kootenay Development Co. has taken a lease on the Silver King mine and the Hall Mines smelter at Nelson. The new company will change the motive power of all machinery to electricity. The lower levels will be unwatered and systematically worked.

According to reports from Nelson, the well known Snowhooe mine, at Phoenix, is about to resume operations.

ONTARIO.

The production of the mines of Cobalt for the first six months of 1905 amounted to 915 tons, which is an increase of 3038 tons over the corresponding figure for 1904. The number of producing mines has increased from 20 in the first half-year of 1907 to 26 in the same period of 1908. The La Rose, O’Brien, and Nipissing are at the head of the list in both tonnage and the amount of smelter returns. During June, 1908, 19 Cobalt mines shipped 1855 tons. The development in Cobalt camp during the past six months has been of a permanent character. Concentrators have been erected at three mines and a custom concentrator started this week. The treatment of the low-grade ores means decreased tonnage but increased smelter returns.
Special Correspondence.

LONDON.
The 'English Rand' Bubble.—Re-organization of Stratton's Indepen-
dence.—Elmore Process at Broken Hill.—Affairs of the Zinc Corporation.

The self-styled 'English Rand,' or in other words, the Chastan Syndicate, Ltd., that was floated by C. F. Kennedy about eighteen months ago, has already come to an inglo-
rious end. At the time of its inception the exact location of this wonderful ore deposit was kept a secret. There is nothing like secrecy when creating a boom. The shares were traded off at high premiums to admirals, generals, and such gentlemen who are prone to think they know more about mining than members of the mining profession. Some of the shares were allotted to people without their knowledge, but it was only after the bubble was pricked that the allottees thought it worth while to repudiate their liability for calls. The deposit is a conglomerate in the iron and coal beds of the Forest of Dean, Gloucestershire. A good deal of money was spent in prospecting, and in some places the assays showed a few pennycweights of gold. Two mining engineers of high standing examined the workings on behalf of their clients who were thinking of taking shares. Their reports are, however, private property, and have not been published. The Company is now at the end of its resources and the directors are all resigning. A meet-
ing is to be held shortly to consider whether more money shall be put up or whether the scheme shall be decently buried. The directors still assert that there are excellent hopes of finding payable deposits, and they also hold the bait of rich iron-ore and mines on the property. There is no reason why, in theory, a 'fossil placer' should not exist in this place, but present indications do not warrant haphazard expenditure in prospecting for it. As regards the presence of iron-ore, this, of course, is a matter of public knowledge. The iron-ore bodies of South Wales and the adjoining counties in England were worked long ago upon their outcrops. In fact, the lines of outcrop are still indicated by the iron industries, which, however, now draw their supplies of ore from abroad or from other parts of England. The only place in Great Britain where the iron-ore asoci-
ated with the coal measures are profitably worked is in the Argyll district of Scotland. On the whole, I am of the opinion that the shareholders in the Chastan Syndicate have been well taken in by the speculations of the Forest of Dean District.

In your issue of May 23 I mentioned the case of Strat-
on's Independence, Ltd., which requires £50,000 more capi-
tal for the new plant for treating the dump-ore, and I out-
lined the scheme for raising the money by the issue of debentures carrying 25% interest and dividend. This scheme has unfortunately not gone through, as less than half the required amount was subscribed. The directors are now bringing forward a proposition to re-construct the com-
p any. As I have several times mentioned, the method of raising money by re-construction and assessment is not popu-
lar at present among directors, owing to a recent decision relative to the rights of dissentient shareholders. How-
ever, in the case of Stratton's, there seems now to be no alterna-
tive. The proposition is to form a new company with a nominal capital of £125,000 in a million shares of 2s. 6d. each, credited with 1s. 6d. paid. The liability of one shilling per share will provide £26,000 if everybody pays up, and the directors feel confident that a sufficient number of shares will be taken to provide the necessary £50,000. The present issued capital is £1,000,000, in 1,000,000 shares of £1 each, and the current quotation varies from 1s. to 15d.

The re-organization scheme brings down the nominal value of the share to its real value. There is reason to think that shareholders ought to pay up, for there is every indication that they will get their money back from the dump, and with the mine put into shape again there is a possibility of further profits being made by the lessees.

In your issue of February 29 last, I gave some particulars

of the present state of the Zinc Corporation, the Australian company which was formed by Dewick, Moreing & Co. for the purpose of utilizing the stacks of zinc tailing at Broken Hill. I mentioned that after trying the Potter and the Cattermole processes without satisfactory results the directors had decided to adopt the Elmore vacuum plant. I have now to report that after five months continuous use, this plant has become an undoubted success, and the pro-
cess promises to establish itself as an important factor in the utilization of ores. It is continuous, automatic, and works at ordinary temperatures. I do not think that most Americans appreciate the process. I will then boldly state that of all circumstances, firstly when the sul-
phides are liable to float away in water-concentration, and secondly when the sulphides and the gangue are of nearly the same specific gravity. The Broken Hill problem comes under the latter category. The galena can be separated in jigs from the blende and the gangue, though not very completely, owing to the intimate mixture of the two sul-
phides, in has been possible to save 60 to 70% of the lead and silver by jiggling, but the zinc tailing has until recently been stacked. The advantage of the flotation pro-
cess is that it will separate the sulphides from the gangue in spite of the similarity in the specific gravities. In oper-
ating the Elmore process, the zinc tailing is first sent to Huntingdon mills and grinding-pans for comminution. The average content is about 20% zinc, and 6% of sulphur is produced. After passing through the Elmore plant a concent-
trate is obtained averaging 45% zinc, 12% lead, and 16 oz. silver. The proportion of zinc extracted is about 80%, but at present the extraction of the lead is rather lower. There has been a steady increase in the capacity of the plant, and also in the extraction, and there is every reason to believe that the figures can be still further improved. At present 1,700 tons are treated per month, yielding 5,000 tons of concentrate. The concentrate produced is not a readily marketable commodity, and the terms offered by the firm of Aron, Hirsch & Son, of Halberstadt, Germany, who have contracted to buy 40,000 tons per year, were not suffi-
cient to yield a good profit. The Company has therefore installed a furnace to driving off the oil, and a set of Wil-
flory tables, for the recovery of silver. This separation can be effected owing to the finer grinding, and to the absence of gangue. The Company does not give exact figures for the grade of the two concen-
trates. All that is said is that in the final zinc concen-
trate the zinc content is raised to 47%, and that 230 tons of lead concentrate are produced per month. The lead content of the zinc concentrate is not given, nor is the method of separating it from the lead concentrate. We are not told either how much zinc concentrate is produced nor how much of the mixed concentrate cannot be separated into separate lead and zinc concentrates. This question has nothing to do with the Elmore process, but it is none the less important to the Zinc Corporation. The cost of treat-
ment is at present about 10s. per ton, and it is hoped to eventually get it down to 8s. The price paid for the tail-
ing that is being worked at present was 5s. per ton. It is estimated that under the present sales contract, the process will begin to pay when zinc is over £17 per ton. The finan-
cial vicissitudes of the Zinc Corporation have been very great, and promise to remain so for some time. In the February article mentioned, it was stated that the issue of £182,000 needed for expansion was to be covered by a separate lead and zinc concentrate. The attempted issue of the remainder has proved a failure, and in con-
sequence the Company has been hard-pressed for funds where-
with to meet the instalments of the purchase money for the stacks of tailing as they become due. In some cases it was possible to vary the contract so as to postpone payment, and in others the options have been abandoned. There has been raised as a loan from the bank, on the security of Lake View Consols, and guaranteed by C. A. Moreing, H. C. Hoover, and F. A. Govett, personally. The Company is naturally badly hit by the present low price of metals. Its future depends to a large extent on the metal market.
JOHANNESBURG. TRANSVAAL.

Rand Mines Reach Billion Dollar Output.—Decreasing Costs and Low-Tenor Ore.—Developments on Upper Witwatersrand.—Records in Shaft Sinking.—Amalgamation of Technical Societies.

With the declaration of the gold output for June, to be made in a few days, the Witwatersrand will have achieved the distinction of an aggregate yield amounting to the commencement of operations in 1887, to $200,000,000. Dividend declarations for the closing half year approximate the record figure of $4,000,000, making the corresponding aggregate of distributions $49,000,000 to date. The results for the half-year exceed the standard for 1907 (when $129,000,000 was produced) by $7,000,000 to $8,000,000 per annum. Considerations of the gold output for the period has been the advance in working-profit. Critics claim that a point to point many causes for the loudly proclaimed 'reduction in working costs' not essentially indicative of higher efficiency, to curtailing of development, to inexpensive extraction of lower-grade ore from the foot-wall of old stopes, and to divers other factors; but it is unquestionable that in conjunction with the improvement of reduction and treatment methods, underground conditions have been materially bettered from an economic standpoint. There is more scientific treatment of the lesser mining problems. The miners themselves are now obliged to give a greater share of personal attention to the running of their machines and to remain satisfied with smaller checks than in the prosperous pre-strike days. Shift-bosses, too, are now recruited more exclusively from the ranks of trained mining engineers. The mine, at last, is beginning to give the fish-see the survey office no longer the best step to a management. The re-organization of methods of underground administration has been largely instrumental in the reduction of average working-costs from $5 or $5.50 to the present average of $4.35 per ton milled. In May, fifteen companies operated at less than $4, and five of these at under $3.50. It is constantly urged that maximum profits, not minimum costs, should always be one of the primary conditions for the prevailing system of forcing the mill to its utmost capacity, and with greatly increased stamp-duty, reduction of grade has been inevitably and generally warranted. The gradual reduction of yield per ton since the war has been from $9.45 to $7.54 per ton.

Those who welcome signs of industrial expansion in other parts of the Transvaal, of which a present embargo is over-centralization, may happily note an advance in the amount of gold contributions from Lydenburg, Barberton, Nigel (virtually a section of the Rand), and other districts. The extreme gold-yield for 1907 totalled $4,500,000, while the rate of production is now $1,000,000 in advance of this figure. While the downward course of working-costs has duly turned the thoughts of Rand managements to the lower-grade blocks of ore, formerly considered unpayable, renewed attention is likewise paid to the few equipped mines between Modderfontein and Randfontein, still inactive. A notable break in this 50-mile chain occurs between the west-central and Roodepoort sections of the Rand, representing the Aurora West, Bantjes Consolidated, and Vopleinstein's Consolidated Deep properties. The Aurora West is being watered, and financial arrangements are being made for the revival of the other two mines. There is yet another direction in which the hopes of the more optimistic may turn without leaving the Rand area, namely, in the ‘banket’ beds of the Upper Witwatersrand formation. The Kimberley and the Elsburg series, containing several feebly-auriferous members, run parallel to the Main Reef, and are the chief source of the gold output of the Rand. Both lines are marked by an abundance of small shafts and trenches, put down in the earlier days, when grade-requirements to ensure payability were higher than now. A few weeks ago, an operator backed by Sir Charles Metcalfe (of Rhodesian fame) and the Rhodes Estate commenced sinking on the Elsburg reefs near the township of this name. Three or four shafts are being put down on a large-pebbled conglomerate bed (characteristic of the series), and average pannings of $3 to $6 are claimed, though my own samplings at a few points do not confirm this valuation. It must be acknowledged, however, that the dozen miles of Kimberley and Elsburg reef outcrops from which good colors can be obtained, having features which closely resemble those of the Main Reef, provide a more attractive area for further prospecting than many distant lands.

In regard to deep-level mining, it is to be noted that the South Rand Co., situated on the dip of the Crown Deep, and the latest addition to the list of active Central Rand companies, has nearly completed its permanent head-gear (104 ft. high) preparatory to the sinking of its vertical shaft. In accordance with the recently-accepted principle, this shaft is being worked until all measures necessary for the future exploitation of the mine, are completed, temporary installations to carry the shaft to a moderate depth being considered uneconomical. The excavation is at right angles to the strike of the formation. The South Rand should cut the reef at about 2100 ft., and its prospects of success, always good in such a favored locality, have been strengthened by highly satisfactory developments in the Crown Deep at its northern boundary. Like those of the Turf, City Deep, and Brakpan mines, its shaft is of seven compartments; it measures 44 ft. 2 in. by 8 ft. 2 in. outside timbers. Progress must be watched with particular interest, for the benefit of widely accumulated experience is now available for the determination of methods, and the vertical shaft of great depth is less likely to appear as a factor in deep-level development than in former programs. In spite of increasing depths of shafts, both the Turf and Brakpan mines continue to record admirable footages. The former, at 2500 ft., now-averages 133 ft. per month, and the latter, in which the world's record of 204 ft. was made last year, and in which breaking-conditions are more favorable, has averaged 163 ft. for the last six months at 1250 ft. to $112 to $142 per foot. This Brak- pan shaft is today 2600 ft. deep.

The Chemical, Metallurgical & Mining Society concluded a year of great practical usefulness at the last meeting, when the chair was vacated by John Yates in favor of R. G. Bevington, who, with his colleagues, will be called upon to work strenuously during the ensuing year to preserve old standards. Rand technical and scientific societies have shared sensitively in the trials of the long-enduring depression, and finance committees have had to exercise unwonted discretion to satisfactorily weather the storm. Questions of economy have largely dominated the proposal for the amalgamation of the Transvaal Institute of Mechanical Engineers and the South African Association of Engineers. Dr. J. L. Laechele, a strong man of the matter, urged that a new body should be formed at the last meeting of the Chemical, Metallurgical & Mining Society in favor of greater co-operation among the various societies and among other things suggested the organization of a joint social club for mining men. This idea might develop, by force of prevailing circumstances, into some scheme of administrative and journalistic co-operation, though the strength of numbers possessed by the less exclusive chemical society, and the antipathy of its council as a whole to any amalgamation threatening to diminish the body's individuality, constitute strong factors opposing closer union in its extreme aspects.

MEXICO.

Mexican Central Extension of Parral.—Inde Consolidated and Guadalupe Gold Mining Companies.—Smelters at Inde and Santa Maria del Oro.—Velardena Plant.—American-Mexican Mining & Development Co. Fiasco.

The first ten kilometres of the extension of the Mexican Central's Parral branch from Rosario, the present terminus, on toward Inde, Durango, has been approved by that State Government, and it is certainly hoped that the same may be promptly built and the entire road pushed on to completion. Parral is now a railhead for horseback ride from Rosario station, and the consequent high freight rates overland keep a number of good mines closed, as less than 100 oz. ore leaves little or no profit. The principal properties at present are the Inde Consolidated Gold Mines Co., and the
SALT LAKE, UTAH.

Blowing-in of Smelter at Tintic—Utah Copper Production for June.

—Boston Consolidated Mining Co.—Smelter at Ogden.

An event last week worthy of note was the celebration commemorating the blowing-in of the new smelter in the Tintic district and which has been built by the Tintic Smelting Co., at a cost of at least $250,000. The plant, however, did not begin operations on the date set for it, for the reason that the constructors were unable to get it ready. But plans had been made for a demonstration, and thereafter the outfitting. Excursions were run into the camp by the Rio Grande and the San Pedro, Los Angeles & Salt Lake railroads, and several thousand people participated in the festivities which were followed by a visit to the mines of the several Tintic camps. It will be at least two weeks, so the officials say, before the smelter will be ready for commission; but in the meantime, custom ore is being received. And of the Tintic mines last week amounted to 114 carloads.

Much interest has been taken in the report of D. C. Jackling, general manager for the Utah Copper Co., showing the June production of that corporation's Bingham mine to have been 4,105,926 lb. of copper, or 34,000 lb. under the record for the previous month. Taking into consideration, however, that there was one less working day in June, the showing is not so bad. All things being equal, the June output would have exceeded that of May by 99,600 lb. The directors of the Company will meet in Salt Lake in a few days to post the dividend, which will probably be 50c. per share. Engineers of the Company are preparing plans to increase the capacity of the concentrator at Garfield to treat 10,000 tons of ore per day, the present capacity being 6000 tons. The Boston Consolidated Mining Co. has succeeded in obtaining a modification of the terms of its contract with the American Smelters Security Co., and has resumed the shipment of ore from its Garfield concentrator to the copper smelter at Ogden. Approximately 900 tons of ore per day is being shipped from the Boston Con. mine for concentration. This output will be doubled by September 15. The Utah mine of Fish Springs paid the usual dividend of 3c. per share, or $900 last month.

The Utah Copper Co. plans to increase the output of its Bingham mine at least 40% within the next year and has made plans to build an addition to its Garfield concentrator to meet the demand. It is also intended to make many other improvements representing a total outlay of approximately $750,000. It is estimated that it will require nine months to complete this construction and that with the new equipment the Company will be in condition to produce from $5,200,000 to 100,000,000 lb. of copper yearly, the production now standing at 60,000 lb. The initial dividend of 50c. per share, or $367,500 is payable on September 30. The treasurer of the Corporation has about $1,600,000 in cash on hand. A recovery of 23 lb. of copper at a cost of 75c. per ton is being made.

The United States Smelting, Refining & Mining Co. is operating four lead furnaces on oxidized charges and by August 15 it is expected to have its new smelter in operation. A change is being made from batch roasters to the converter-roaster in order to make less acid in the fumes, which it seems, can be neutralized by the operation of the Company's new patented zinc-oxide process, thereby eliminating danger to vegetation. It was upon this representation to the court that the injunction resulting from the trial of the late smelting company's suit against the American Smelters Security Co. had been obtained. The company have resumed smelting ores. The United States lead mines at Bingham are producing again and the low-grade product is being treated in the concentrating mill near the smelter and which has capacity for 300 tons per day. The Uncle Sam Consolidated Mining Co., operating in the Tintic district, will resume dividend payments again this month after a recess of about six months. There is nearly $46,000 in the treasury, with production going on steadily. A shipment of 50 tons marketed last week brought net returns of $180 per ton.

The copper smelter near Ogden, leased recently to the Independent Smelting Co., has been placed in commission again. One copper furnace is in use and the second will be within a fortnight. The plant was erected by the Utah Smelting Co. and operated several months last year as a competitor of other Utah smelters, but the venture proved unsuccessful from a financial viewpoint for the reason that a large tonnage of ore, bought during high metal-prices, could not be moved before serious decline had occurred. Besides the Company had several unprofitable ore-contracts on its hands. The smelter had been closed about a month before the last half of the year, and since then the equipment was going idle and captured their money while many good men went begging.
The Boston & Montana Co.'s mines were operated at about 40% of their normal capacity during July, the reduction being due to the shut-down of the company's smelter at Great Falls as a result of the damage done to the plant by the June floods. Because of the restricted output of the Boston & Montana, the copper production of the Butte district was again considerably below normal for the month. The output was 26,235,300 lbs., against 13,155,900 lbs. in June. It is expected that the Boston & Montana smelter will be in commission again by the middle of the month. The daily ore tonnage, yield of copper per ton, and the daily average copper production for July were as follows:

$37,125 = 26,235,300$

The Tuolumne Mining Co. is one of the first of the newer concerns to develop pay copper ore. At a depth of 1000 ft. in the Tuolumne claim, just south of and adjoining the Jesse mine of the North Butte Co., extensive exploration has been done, and some really good ore has been cut in the first vein south of the shaft. The vein at that point is 26 ft. wide, and there are 4 ft. of ore on the hanging wall and 2 ft. on the foot wall, assays from which showed 33.1% copper, 20 oz. silver, and 80c. in gold per ton. The Company is preparing a foundation for a complete new surface plant, including a 22 by 60-in. Nordberg, first-motion engine, with a capacity to work to a depth of 5000 ft.; three new boilers of 250 hp. each; a 15-drum compressor, and a new head-frame.

The Raven Mining Co. has resumed shaft sinking, and will carry the incline from the 1100 to the 1300-ft. at least. At the same time development on the 1329-ft. level is being continued. At a meeting of the directors of the Butte & Arizona Copper Mining Co., held in Butte, it was decided to resume operations at the mines in Arizona immediately. The property of the Company is situated at Hereford, about 35 miles from Bisbee, and as soon as supplies can be taken to the camp work will begin. Since fire last spring destroyed the surface building and the Company's supplies, the mine has been closed. The property is being opened by an adit, now 2390 ft. long, and it is expected that the vein will be reached at a depth of 550 ft. from the surface in about two months.

The recent negotiations to raise funds for resuming work on the Butte & London seem to have failed, and there are no prospects for an early improvement in the affairs of that Company. The Coloma-Leavitt suits work early in the period of the panic last year, because a New York firm which had made promises and efforts to finance several new Butte companies failed to come to the rescue. The Relna Copper Co., which passed into the control of Colonel Guffey and associates of Pittsburgh, may get on its feet again if the $50,000 bond issue is successful. The stock of the North Butte Mining Co. has been a spectacular feature the past two weeks, but the rapid advance has not been surprising to the people of Butte among whom the merits of the North Butte are known. The Company is certainly producing copper, at a cost little in excess of 7c. per lb., and its monthly output is more than 4,000,000 lbs. The Company has a capitalization of only 490,000 shares, and the advance of one cent per pound on copper means a great addition to the earnings. The North Butte is claimed by many to be the greatest copper mine in the world. There is one other property in Butte that will some day rival North Butte, and that is Butte Coalition. The latter is producing a quality of ore almost uniformly as rich as that of the North Butte, but the production is at present limited to about 500 tons daily. By the first of July, with the completion of the development now being done through the Tramway shaft, the output will be fully 2000 tons per day, counting on only the Minnie Kealey and the Harus mines. In addition to these two mines, however, the Coalition gets a share of the profits from the ore mined by the Boston & Montana in the Red Penn ground, and from the Pover Co. on ore mined from the Niper vein.

H. V. Winchell, former chief geologist for the Amalgamated Co., who left the employ of that company to fill an engagement with the Great Northern railway in a similar capacity, is no longer connected with the Hill interests. Mr. Winchell achieved a great reputation as a geologist through his connection with the Amalgamated. During his employment by the Great Northern railway, Mr. Winchell devoted considerable time to developing cases against small companies and small individual mineral holders in the Butte district, his contention being that the Great Northern and the Northern Pacific owned the mineral rights claimed by others, and several actions are now pending to determine the question. Mr. Winchell also acted as consulting engineer for the Butte & London Mining Development Co., and it was on his judgment that the Company conducted its development.

The Copper Eagle Mining & Smelting Co. has resumed operations, work being confined to the Eagle claim, upon which there is a shaft 265 ft. deep, with 390 ft. of drifts at the 200 and 250-ft. levels. With this superficial development the Company has shipped 433 tons of ore from the 250-ft. level, having a net value of $53,95, and 456 tons from the 250-ft. level, having a value of $23,000.

**PARK CITY, COLORADO.**

**Developments on Engineer Mountain. --- Shipments from Highland.**

Chief.—Hanna Mining & Milling Co.'s Equipment.—Rich Ore in Cinnamon Pass.

With the drop in metal prices last fall, shipments of ore from Hinsdale county, which had become larger than for a number of years past, practically ceased, and the year 1907, which had opened with great activity and unusual promise for this district, also witnessed the cessation of mineral output. This part of the world, however, is used to being hard hit, and when an edict was asked how Lake City was standing the panic, he replied: "Fine; she has been in training for it for 25 years." Hinsdale county takes punishment remarkably well, and notwithstanding the deadening effect of the decline of metal prices, development work to some extent was carried on during the past winter in 27 properties, situated in various parts of the county. Notable among these were the Frank Houck, Highland Chief, Peltz, Panny Fern, Clara L., and Great Ohio. Along with the melting of the snow work was renewed here and there.
throughout the county. The exact conditions today are rather encouraging, for while there is little production, there is considerable well-directed development, which augurs well for the future. Perhaps the most interesting revival is that of the Frank Hough mine, situated on Engineer mountain, or the American Flats. The Frank Hough was closed down in the fall of 1886, after having produced several thousand tons of ore containing 25% copper, 0.5 oz. silver, and one-fourth ounce gold per ton. The statements relative to the ore left in the mine are rather vague. It is known, however, that in the lowest workings, less than 400 ft. from the surface, there was uncovered a rich of ore for a length of about 1700 ft. silver per ton. This mine has for several years periodically shipped small lots of high-grade ore, and its further development is of importance to the vicinity.

In 1881 the Hinsdale county slopes of Engineer mountain and the American Flats bristled with a forest of stakes, erected by an army of crstwhile 'peggers.' The hardest work they did was to place the stakes, and the larger part of that promising region is still waiting for pioneer blasts. It is known from reliable sources that there are numerous outcrops of veins in this district which carry gold from 0.25 to 9 oz. per ton, yet no one has undertaken development except the places mentioned. The Highland Chief mine on Sheep mountain is now a steady shipper of carbonate and sulphide of lead ore. This property has been operated for the past two years. The mine is developed to a depth of 190 ft., and has been a shipper from the start. In the 190-ft. level an ore-shoot averaging about 4 ft. wide has been uncovered 220 ft. in length. Both breasts of this level show the same width of ore. The Independence, an adjoining property, on the end line of the Highland Chief, probably the same vein, and producing the same class of ore, is again being operated after a shut-down of nearly a year. The Hama Mining & Milling Co., owning the Moro and other property near Capitol City, is about to let contracts for 700 ft. of development work on the vein. This company has expended a large sum of money upon surface improvements, including an aerial tramway, a hydro-electric power-plant capable of generating 1000 hp., and in remodeling and adapting its mill to treat the complex sulphide ores. These improvements were completed last season and several hundred tons of ore tested in the mill resulted in a close saving of the metals in the ore. The development of the mine had not kept pace with the milling facilities, and the company became financially involved; hence a shut-down occurred early last fall. G. H. Martin, the energetic manager of the company, has succeeded in keeping up a high standard of its already excellent management, and has also raised a fund for the further development of the mine. The Ute and Ulay and Hidden Treasure mines are closed. There has been a rumor of a consolidation of these well-known silver-lead producers. A fair amount of prospecting is being done throughout the Henson Creek region, and some favorable results are reported from time to time.

There is renewed interest in the Cinnamon Pass and Cleveland Gulch districts. Since the closing of the Isolde, several years ago, this region had been almost abandoned until the spring of 1907, when Lake City people commenced negotiations for a lease and bond on the Hollister and Inez claims. These parties are starting a cross-cut to prospect the ground below the Isolde shoot, which dips into and was partly mined in Hollister ground. This vein—the Cinnamon fault—in its course to the northeast passes through a part of the Detroit claim in San Juan county and enters the Hollister through its southwest end-line, passes out of the northwest side-line of that claim into the Isolde ground, which it traverses for a short distance, and again passes into the Hollister through the same side-line. The rich outcrop of the Isolde was 30 ft. northwest of the Hollister side-line. The shoot was mined to a depth of 80 ft., and is said to have produced high-grade gold (telluride) ore to the value of $125,000. Three hundred and twenty-four tons of this ore averaged 10 oz. gold and 18 oz. silver per ton.

The property of the Dupre Co., comprising several claims of the group which includes the Isolde, is under option to Silverton, Colorado, and Detroit, Michigan. A payment of a large part of the purchase price has been made. Under this option the vendees cut a vein of seven-ounce gold ore, cross-cutting in the Isolde northwest from the old workings. James H. Sloan, owner of the Fairview claim, situated on the ridge between Cleveland Gulch and Horse-shoe Basin, said to be on the Cinnamon fault, recently discovered some rich free-gold rock in doing surface-prospecting on his claim. From the Isolde on Cinnamon Pass to

Lake City, Colorado.

the Golden Fleece at Lake San Cristobal, a distance of 13 miles, the main range in Hinsdale county having an elevation above sea-level of 11,000 to 13,000 ft., has been but little prospected. There are but few patented properties in the high range between the places mentioned, and only here and there a prospect hole, yet high-grade gold ore float is frequently found all along this range.

The Mexican-American Co., said to be controlled by Englishmen, has secured the Black Wonder property at Sherman. Gen. F. Joubert Pienaar, who served under Joubert in the Boer War, is in charge. Gen. Pienaar has taken an option on the Sterling group at the head of Cottonwood gulch. In 1874 Enos T. Hochkiss and associates located the Golden Fleece, then the Hochkiss mine, and Joel K. Mullen staked the Ute and Ulay veins. The first-named gained a world-wide reputation later on as a high-grade gold mine, and the Ute and Ulay have produced a large tonnage of silver-lead ore. Following the advent of Hotchkiss and Mullen, Lake City became the chief town in the 'Silver San Juan,' and was the distributing point for a large area. In the early eighties the railroads began to crowd out the 'bullwhackers' and the 'muleskinner,' reaching out into the San Juan country, to the towns of Silverton, Ouray, Telluride, and Rico, but left Lake City a 'stage-town' until August, 1889. Since then, Hinsdale county has not kept pace with the other San Juan counties in the development of its mineral resources. Modern transportation facilities diverted investors to more easily accessible places. The reputation of the county has also suffered from ill-advised mining schemes, and from much inefficient management, so that its really splendid mineral-resources have not received the attention they deserve.
Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Dacite as seen at Goldfield is only a quartz-bearing andesite, and is not similar to the highly silicious dacitic rhyolites of Tonopah. It consists of labradorite, hornblende, biotite, augite, and quartz in the usual andesite groundmass. It is much more decidedly porphyritic than the andesite of the region, which otherwise it closely resembles. By analysis it shows 60% silica, which-classes it with the neutral rocks, instead of the acidic eruptives.

Settlement of slime in a small cyanide plant involves dispensing with mechanical apparatus. A series of vats, square or round, with vertical sides, should be constructed so that the pulp-stream may be diverted from any one vat while it is being discharged. The pulp should flow successively through the entire series, and should enter each vat at the centre, and discharge equally around the entire periphery into suitable launders. Thus the velocity of current is checked to the utmost, so that it will deposit its load of solid matter. The vats may have conical bottoms or not, according to the expense justifiable by the conditions of ore-value and capacity of plant. Conical-bottom vats are more costly, and also require expensive supports, and would hardly be used in a small plant.

Cement tables have been revived at the San Pros-pero mill in Guanajuato, Mexico, and renewed testimony to the efficiency of such a surface for concentration is forthcoming. The practical difficulties have always been to secure a perfectly smooth surface. This can be done by making a wooden form against which the cement may set, saturating the form and trueing it up while wet, and applying it to the cement with proper provision for keeping it saturated for several days. The proper mixture of sand and cement will vary with the size and character of the sand. By remembering that the ideal concentrating surface is ground plate-glass, the best attainable mixture for the cement can be easily reached.

Retaining walls are usually proportioned by an empirical rule, although a number of theories, resulting in theoretical formulas, have been advanced. All of these, the best known of which are Coulomb’s, Weyrunch’s, and Rankine’s, depend upon the three following assumptions: first, that the surface of rupture along which the embankment tends to slip is a plane; second, that the point of application of the lateral pressure of the earth is at a distance of one-third the height of the wall from the bottom, which is equivalent to assuming that the variation of the pressure in a mass of earth is the same as in a liquid; and third, an assumption of the direction of the line of action of the pressure (different in each theory). Because of these assumptions, and of the fact that no reliable experiments have verified the conclusions made, no theoretical formula is of much practical use to the designer of retaining walls. Benjamin Baker, an eminent English engineer, says, “Experience has shown that a wall, to sustain earth having a level top surface, the thickness of which is one-fourth of its height, and which butters 1 or 2 in. per foot on the face, possesses sufficient stability when the backings and foundation are both favorable.” Many engineers make the thickness of retaining walls equal to 0.33 or 0.4 the height, using a small batter on the face. A majority of the failures of retaining walls are due to defects in the foundation rather than in the design of the wall.

Nevada law relating to location of placer claims, which include oil claims, requires the posting of a notice on a tree, rock in place, post, or monument, giving names of claim and locator, number of feet or acres claimed, and the date. On unsurveyed land the surface boundaries must be marked in the same manner as in locating quartz claims, but on surveyed land, the initial monument or location notice is all that is required. Within 90 days after posting the notice at least $20 worth of work for each claim of 20 acres or less must be performed, and record must be made with the District or the County Recorder. To take 100 acres of land by one location an association of 8 persons is required. One person, however, may locate as many claims as he desires.

For hardening high-speed tools the barium-chloride process has many advantages. Commercial barium chloride, to which about 2% of sodium carbonate has been added, is melted in a graphite crucible and raised to a temperature of 2000 to 2125°F. The tool is kept in the bath until it attains the temperature of the bath and is then quenched, preferably in an oil-bath. The superiority of this process over a lead-bath or a gas furnace lies in the fact that when withdrawn from the barium-chloride bath, the tool is covered with a thin film of the chemical which prevents oxidation. Taps, threading dies, and other delicate tools hardened by this process retain their size and sharp cutting edges and it is claimed the difference between a hardened and an unhardened tool cannot be detected by inspection.

Speculative locations of mining claims, as distinct from locations made as a result of actual discovery of mineral, could rarely be discriminated against. Failure to mark the limits of the claim in the case cited would be the only omission of serious import, as viewed in the light of California law, and the claimant could probably hold against all comers, at least so far as related to any lode approximately coincident with the lode-line claimed. Another locator posting a notice on a point of discovery outside the limits of the junior statutory claim, and on a distinct lode, might make good his pretensions to his vein up to the lode-line staked in the earlier imperfectly marked claim. Dispossession of a person having evidence to offer of prior actual occupation of the land, however, is repugnant to the principle of law, and to the spirit of the courts, and it is unlikely that judgment would lie against a claimant for imperfections in the details of his location.
Discussion.

Readers of the Mining and Scientific Press are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

Mining Claims on Forest Reserves.

The Editor:

Sir—I have read with great interest your editorial on mining claims within national forests in your issue of July 4. While I appreciate your earnest desire to promote the interests of legitimate mining development on the national forests, I feel that it is to be greatly regretted that statements without foundation in fact should be given the weight of authority by your publication. I have particular reference to the statement that no patents can be obtained to mill-sites within national forests. The Act of June 4, 1897 (30 Stat., 11) provides: "Nor shall anything herein prohibit any person from entering upon such forest reservations for all proper and lawful purposes, including that of prospecting, locating, and developing the mineral resources thereof: Provided, that such persons comply with the rules and regulations covering such forest reservations."

Even if any part of the Act of June 4, 1897, might be technically construed to prohibit the patenting of mill-sites within the national forests, the whole purview of the act is plainly in favor of a proper development of mineral resources. For this reason both the General Land Office and the Forest Service have, contrary to your intimation, construed the law liberally and have assisted bona fide claimants to secure patent to such lands in a large number of cases. Certainly there is nothing in the rules and regulations covering national forests which in any way prevent the patenting of mill-sites. I quote from page 49 of the 1908 edition of the Use Book containing the regulations and instructions for the use of the national forests: "In examining and reporting upon mill-sites, forest officers should keep in mind the following essentials of the law: Mill-site claims must not embrace more than 5 acres, and must be non-mineral and non-contiguous to a vein or lode, and must be used or occupied by the proprietor of such vein or lode for mining or milling purposes. The owners of a quartz mill or reduction works, not owning a mine in connection therewith, may also receive a patent for his mill-site." And again, from supplemental instructions issued forest officers: "Five acres of non-mineral land, not contiguous to the vein in a lode claim, may be embraced in a mineral application for such claim when such lands are used for mining or milling purposes in connection with the claim. Examples of such uses are the locations of mills, of bunk or eating houses for miners, of houses for the storage of implements used in developing the mine, or in the extraction of mineral from the ore."

I trust from these facts that you will appreciate how incorrect your statement is concerning mill-sites.

The Forest Service appreciates the necessity for intelligent examination of mining claims, and so far as the limited appropriations permit, experts for this purpose are employed. At present, twelve mining engineers, either graduates of well known mining schools or men with years of practical knowledge, and six geologists in co-operation with the United States Geological Survey are assigned to the mineral work on national forests. It is hoped to largely augment this force in the near future. It is the policy of the Forest Service to encourage the legitimate development of mineral resources in national forests. To this end it is the duty of forest officers to assist claimants who have made valid discovery and location in good faith: but it is equally important (and I am indeed glad to note that you have emphasized this point), in the interests both of the United States and bona fide miners, to secure the cancellation of fraudulent claims. Adverse efforts of forest officers are directed against claims which are apparently fraudulent, and you will certainly agree with me that no greater service could be rendered to legitimate mining than by protecting it against the exploitation of such claims. Although the General Land Office, and not the Forest Service, is vested with the power to pass upon claims, and, in so doing, necessarily construes the law, I believe that there is no difference between such construction in regard to lands within and those outside national forests. It is true that forest officers assist in investigating the facts of cases arising within the forests, but such investigation should, and I believe does, make the final decision more certain to be just. The interpretation of the law, however, is no more strict. In view of the great importance of the mining industry on national forests, the Forest Service welcomes your helpful criticism. I trust, however, because of the wide publicity given your editorial, and the consequent misunderstanding, that you will correct the misstatement noted.

W. L. Hall,
Acting Forester.

Washington, D. C., July 16.

Sir—I have a recent issue of the Mining and Scientific Press I note an article on 'Mining Claims on Forest Reserves' which contains several statements that are misleading and unfair to the Forest Service, and I request you to consider the following facts in relation to the position of the Forest Service in this matter. The statement is made that many mineral applications are examined and reported upon by rangers inexperienced and with no proper qualifications for the work. At this time all applications are examined by expert miners or geologists specially selected for the work, and every opportunity is given the applicant to show the character of the claim and the work done thereon. The mining laws as interpreted by the Land Office rule in all cases, and if these rulings are not always satisfactory to the claimant it is the fault of the laws and regulations and not of the Forest Service. You state, "there is now no provision for acquiring a patent title to a mill-site in a Forest Reserve," I quote you the instructions given on this subject in the Forest Service
Use Book for 1908, as follows. "In examining and reporting upon mill-sites, forest officers should keep in mind the following essentials of the law: Mill-site claims must not embrace more than 5 acres, and must be non-mineral and non-contiguous to a vein or lode, and must be used or occupied by the proprietor of such vein or lode for mining or milling purposes. The owners of a quartz mill or reduction works, not owning a mine in connection therewith, may also receive a patent for his mill-site."

As a Forest Supervisor I have never received any instructions contrary to the above, and you certainly have been misinformed in this instance. In connection with my duties I have reported favorably on applications for patent for mill-sites, and the Forester has approved my reports and passed the applications up to the General Land Office for patent. If this statement be doubted I can give specific cases to prove its accuracy.

There is no desire on the part of the Forest Service to cripple the mining industry in any manner, and all bona fide applications are carefully investigated and given fullest consideration, as it is recognized that the mining industry means much for the future of the West today as it has in the past. I believe if the men in charge of the national forests were given the opportunity to explain the policy of the Forest Service occasionally instead of hearsay statements being published without foundation, the policy of the Forest Service would be more fully understood by the people at large, and they would find that the national forests are created and administered to give the fullest use of all resources compatible with the permanent preservation of the same.

L. A. Barrett.

Plumas National Forest, Quincy, Cal., July 22.

Cornish Pumps.

The Editor:

Sir—If 'Old Timer' understood the air-chamber to have been applied to Cornish pumps operated by beam-engine, I can quite appreciate his gentle sarcasm in the selection of his signature from the article in your issue of May 2. 'Old Timer' is quite right; it would not be of advantage to put air-chambers on beam-engine-driven pumps, and I certainly would not recommend it. Mr. Herzig, in your issue of July 18, describes the effect of one application of the sort, and its failure. I have some of the indicator cards he mentions, and they surely indicate the fact that air is an elastic and resilient commodity. One or more portions of the pump declined to accept the treatment imposed on them by the fluctuating pressures in each separate down-stroke of the plunger and went out of business. In reply to the query as to why the small pipe-connection was made between the air-chamber and rising column, it may be replied that it was for the purpose of maintaining a regular or definite volume in the air-chamber. These were the pumps driven by the crank-shaft geared to the engine. It was found that the volume of air in the chambers was a fluctuating quantity, and the effect of fluctuation was that when the air-spring or cushion was too long, if I may so describe it, the water-column acted precisely as though it were resting on a long spring, and rose and fell, perhaps three or four times, during the down-stroke of the plunger, a distance of from 6 to 18 in. This was rather too violent for comfort, and the pump-man would have to go below and close off the charging-apparatus. After a time the air in the chamber would diminish in volume, and the pumps would begin to 'snap,' when the air-charging apparatus would have to be opened again. It was found that a certain height of air in the chamber was required to make the pump work as smoothly as desired, and this height being ascertained the chamber and rising column were tapped, and a small pipe connected. The charging-apparatus was then opened, and the excess of air passed through the small pipe, and the troubles of the pit-man from that source were over.

One feature of the application of the beam-engine pump at Loddon Valley interested some of the engineers who saw it. It had no balance bob. The pump-rod was estimated to have some excess-weight over the water-column, and while the exact weight of the rod was not known, about 3½ tons of cast-iron weight was added to the rod to cause it to act with enough promptness on the down-stroke to afford the desired number of strokes per minute. At the top of the shaft on the pump-discharge pipe was placed a tee, to the branch of which was bolted a valve from which a bend led to the discharge-race common to two 26 in. diam. crank-and-gear-driven plunger-pumps and the 24 in. diam. plunger and beam-engine pump. On top of the tee was bolted an extension of the discharge-column, forming simply a stand-pipe, open at the top. The overload on the rod had the effect of starting the downward stroke promptly. Now in order to gradually absorb or counteract the tendency to acceleration of the excess-weight before the lower end of the stroke was reached, the valve was partially closed and the water that was not discharged through the valve simply rose in the stand-pipe. The stand-pipe, 18 in. diam., being but slightly more than half the plunger area, responded more rapidly to the variation of head than had it been larger, the amount in any case being according to the adjustment of the valve, which need be changed only when desired to alter the rapidity of pump-action. This device controlled the action of the pump-rod rather nicely, the cycle of operation being as follows: the stroke of the 24-in. plunger being 8 ft. means a volume of about 150 imperial gallons passing up the discharge-column in say three and a half seconds; should the valve be now adjusted to pass 80 gal. in the three and a half seconds the other 70 gal. will rise in the stand-pipe, and during the remaining three and a half seconds will pass the valve, leaving the pipe empty for the next stroke. The operative effect will be readily understood when it is remembered that each added foot to the height of water in the discharge-column or stand-pipe means 196 lb. taken from the effective weight of the pump-rod and plunger. The stand-pipe was about 36 ft. high, and to close the valve entirely was to practically stop the pump.

In the letter in your issue of January 18 mention...
was made of the comparative costs and economies of different pumps being determined by graphic analysis, and in extension of this a diagram is here with submitted that shows in a graphic manner what many words would not entirely cover. It is a statement of estimates based on conditions of material supply, labor, and operation, obtaining in the Deep Leads district of Victoria, Australia. Some familiarity with conditions there enables the writer to state that the diagram is an expression of the actual facts of cost and operation, subject only to such corrections as may be required to meet differences of location, installation, and operation, due to competitive or economic conditions. The efficiency or duty of each of the several pumps noted, excepting only the steam-pump, is based on actual everyday operation of the four types, all of which were running within 20 miles of each other. The expense of the steam-pump is based on the guarantee of a reputable pump-maker, and while it may be ‘a bit fine’ for everyday results it is important. The diagram was made up to simplify the decision on the selection of an installation to pump 2,500,000 imperial or 3,000,000 U. S. gal. per 24 hours from a mine 600 ft. deep. The total first-costs to purchase and install each of the plants is expressed in the nearest one thousand pounds sterling, and the diagonal lines, starting from the first-cost, indicate the additional cost for continuous operation during a period of five years.

As to efficiencies or duties of the several plants, upon which must be based all running-expense costs, it must be apparent that the most efficient is the most economical in the long run. The most economical plant that can be installed, is, so far as has been determined, one that is driven by high-duty, compound-engine, rope-drive connection to gear-train and crank-shaft, and connected to Cornish plunger-pumps by the usual sweep-rods, balance-bob, and pump-rods, similar to the installation described by Mr. Herzig in your issue of July 18, as having been put in the Berry United mine at Ullina. It should give a total combined efficiency of at least 80% from the throttle-valve of the engine to the water delivered at the pit-mouth, and do it every day of the year. By ‘total combined efficiency’ is meant that 2,500,000 imperial gal. per 24 hours raised 600 ft., represents 315 hp. of work done, and, at the efficiency named, the engine would indicate but 395 hp. At a ‘total combined efficiency’ of say 42%, the appropriate percentage for an electric-driven centrifugal-pump of equal capacity, the engine would have to indicate 740 hp., or nearly twice as much fuel would have to be burnt in the boilers to keep the engine going. The ‘erected costs’ include everything to make a complete plant of the sort and style named, ready to run. As the principal item of cost used in making up this diagram, fuel is figured at 7s. 6d. per ton, and management, salaries, wages, repairs, and maintenance at a rate appropriate to the scale of development and operation calling for the installation of a pumping plant of such capacity. The steam engines, both for generator-plants and Cornish pumps, are set down as having a steam consumption of 18 lb. per horse-power-hour. I am well aware that a better figure than this can be shown in a running test, and it is probably beaten in many large plants that are running on a commercial basis, but in a pumping plant in a mine, running day after day, stopping but one or two hours once a week for examination and adjustment, it will be found that 18 lb. of water evaporated per each indicated horse-power will not be too high. The fuel consumption of the beam-engine plant is placed at exactly the figure determined by the operation of three beam-engine plants in Victoria. It amounts practically to a fuel account of 13d. (26c.) per day per horse-power.

One centrifugal-pumping plant operated in Victoria did not give an efficiency of 42 1/2%, nor anything like it. As a matter of fact, its ‘total combined efficiency’ was almost exactly 32%, and every 100 hp. of water delivered by this pump simply meant an expenditure of enough fuel to supply the generator-engine with steam to indicate 312 hp. The diagram will now afford intelligent comparisons. The cheapest plant to install is the steam-pump, but its total expense equals that of the most expensive plant to install in a little more than two years’ operation. The beam-engine plant is the next cheapest to install, but its total expense equals that of the most economical in less than 18 months’ operation. Note the difference in favor of the compound-engine-driven Cornish pump-plant at the end of say four years. It has run into a total expense of less than £49,000; the beam-engine plant £58,000; the steam-pump plant £67,500; and the electric-centrifugal £71,500. While this diagram illustrates certain conditions for which
it was specially intended, it will also serve as a guide in making comparisons based on other conditions, for the relations of one to another will remain practically the same. It must be modified by the different proportions of volume and lift, and by the percentage of charged expenses for pumping and other operations. The diagram will also illustrate rather clearly the kind of plant to be recommended. It scarcely need be said that where electric current can be generated by water-power and led to the mine at some much cheaper rate than it can be generated at the mine, there would be good reason for putting in centrifugal or geared pumps. In this case, then make comparison of the installation and operating expense of Cornish pumps, motor-driven, and in doing so, remember the high efficiency, about 90% of the water-ends of the latter against about 70%, at the outside, of the centrifugal.

E. P. JONES.

San Francisco, July 28.

A Farmer’s Inquiry.

The Editor:

Sir—When my brother Ike got me to buy some mining stock for $3 a share a year ago he told me it was the chance of my life. He wrote that all the insiders were buying this treasury stock so that the company could build a mill, and that when that was done big dividends would be paid. Ick wrote that I would be a fool not to use his tip. Well, I bought some stock and the mill was built, but I have made none of money yet, and my $3 shares are down to 75c, though lately they have gone up a little. I have pretty near lost my faith in mining stocks. Of course I know Ike meaunt well by me. There’s one thing I got out of it, and that’s a nice annual report with plenty of figures and a pretty map. But I can’t understand these figures very well, and I want to know if you, Mr. Editor, who seem to know everything and a little more, about mines and mills, won’t help me in my trouble.

I find in the report a very plain statement that the mill worked 34,484 tons of ore out of which they made a profit of $165,788, and I am very glad to see this. But when I come to find out what they have on hand I see this item: “Estimated amount expended for development in advance of mining carried forward to next year, $50,000.” Now I want to know if that does or doesn’t cut into their profits for $50,000? Then I see they value their property at $3,000,000 and more, but that they only allow for a depreciation of $15,028, and this on their ‘mine equipment,’ which cost $45,117. They don’t allow any depreciation for their mill, which cost $414,945. Is it a fact that mining equipments wear out and that mills last forever, as this seems to mean? Also I want to know if you think a firm of public certified accountants should pass a statement of this kind without making any comments on it? As the shares of this company are now selling for $1 on the market, or a value for the property of only $2,000,000, while the value on the books is $3,000,000 and over, would it not be a good plan for me to buy some more stock? It seems to me that even if I allow a large margin for shrinkage they can at any time sell their mines with its shafts and tunnels, all of which I judge are valuable from their system of valuation, for more than the $1 per share. Ike tells me that the mine is all right and will soon come out, and that the reason they have not done better is that the former managers probably made mistakes. He says all I have to do is to hold on. What do you advise me to do?

Huntsville, Missouri, July 20.

Joseph Bowers.

Professional Ethics.

The Editor:

Sir—Relative to the discussion of the proper ethical standard to be adhered to by engineers, I venture to suggest that unless the engineer himself maintains in his own private life and business relations the high standard that should be the rock-ribbed foundation of his reputation, no set of rules that can be prescribed can have much influence on either his good faith in dealing with his client, or the slowly-formed estimate of his character and ability that comes only through long scrutiny by the public. Without the foundation of character, no man will be honest except through fear, and this kind of honesty is worthless. A strong and clean personal character, inherently capable of discrimination between right and wrong, needs no written code. The engineer must be to some extent his clients’ moral guardian, for, while no act of his own should inure to his benefit to the detriment, however remotely, of his clients’ interest, it is hardly necessary to remark that in many cases the honest engineer, however strong the contrary influence, must decline to follow the course most agreeable to his clients’ desires or financial profit. The function of the engineer must be judicial, and his attitude should be as free from personal bias or considerations of mere expediency as that of a justice on the bench.

Regarding mining reports, I believe the only safe and consistent course for an engineer who desires to remain above suspicion is to represent only the purchaser in the examination of a mine that is offered for sale. It seems to me well worth while for the engineer to rigidly refrain from anything in the way of mine-valuation except as the representative of the purchaser, or in consultation with an owner who has received an offer, and requires independent advice as to its acceptance. Aside from these two phases of mine-valuation, the function of the consulting mining engineer might properly be confined to advising on the development, equipment, and operation of mines and metallurgical works. This is a field broad enough for any man, whatever his ability or activities, and that embracing risky or even doubtful connection with the sale of mines or stock can well be entirely avoided and left to that class of practitioners having less scruples.

Los Angeles, July 20.

George Sydney Binckley.

The death rate of those employed in the mines and quarries of the United Kingdom during 1906 is officially given as 1.29 per thousand, as opposed to 3.21 in the United States.
The precipitated sulphides are discharged with treated residues. Some silver is always precipitated in the zinc-boxes as sulphide, at times enough to cause trouble in melting the precipitate. Mercurous potassic cyanide, K\(\text{HgCy}_3\), dissolves silver sulphide as follows:

\[ \text{Ag}_2\text{S} + 2\text{KAgCy}_2 = 2\text{KAgCy}_2 + \text{Hg}_2\text{S}. \]

The salt is very unstable, and must be protected in solution in its mercurous state by the presence of some reducing agent, such as ferrocyanide of potassium. The latter salt is generally present in mill-solution, and consequently need not be added in practice. Mercurous potassic cyanide, in the presence of free alkaline hydrates, also readily dissolves stephanite, \(\text{Ag}_2\text{S}_3\text{Sb}_2\), pyargyrite, \(\text{Ag}_2\text{S}_3\text{Sb}\), and proustite, \(\text{Ag}_2\text{S}_3\text{As}\). I am of the opinion that the reactions taking place in this solution are as illustrated by the following equations:

\[ 2(\text{Ag}_2\text{S}_3\text{Sb}_2\text{S}_3) + 20\text{KAgCy}_2 + 4\text{Ca(OH)}_2 = 20\text{KAgCy}_2 + 10\text{HgS} + \text{Ca}_2(\text{SbS}_3)_2 + \text{Ca}(\text{SbO}_2)_2 + 4\text{H}_2\text{O}, \]

and

\[ 2(3\text{Ag}_3\text{S}_3\text{As}_2\text{S}_3) + 12\text{KAgCy}_2 + 4\text{Ca(OH)}_2 = 12\text{KAgCy}_2 + 6\text{HgS} + \text{Ca}_2(\text{SbS}_3)_2 + \text{Ca}(\text{SbO}_2)_2 + 4\text{H}_2\text{O}. \]

The formation of the salt \(\text{KHgCy}_3\) in practice is best made by adding calomel, \(\text{Hg}_2\text{Cl}_2\), to the cyanide solution:

\[ 4\text{KCy} + \text{Hg}_2\text{Cl}_2 = 2\text{KAgCy}_2 + 2\text{KCl}. \]

In the absence of free ferrocyanide of potassium, or other reducing agent, mercuric potassic cyanide is formed and metallic mercury precipitated:

\[ 4\text{KCy} + \text{Hg}_2\text{Cl}_2 = \text{K}_2\text{HgCy}_3 + 2\text{KCl} + \text{Hg}. \]

In ordinary practice the ore is first subjected to treatment with solutions of potassium or sodium cyanide until all or about all of the possible extraction has been obtained; then mercurous chloride is added and the treatment continued to the end. The only serious interferences I have encountered in the use of mercurous potassium cyanide, are manganous compounds. They immediately oxidize it to a mercuric salt, destroying its usefulness as a solvent. The salt does not dissolve gold. Its use is covered by letters patent in the United States and foreign countries.

When there is enough ferrous iron in the ore to cause a serious interference, the salt is best formed by adding mercuric chloride to the mill solution:

\[ \text{K}_2\text{FeCy}_4 + 2\text{HgCl}_2 = \text{Hg}_2\text{FeCy}_4 + 4\text{KCl}, \]

and

\[ \text{Hg}_2\text{FeCy}_4 + 2\text{KCy} = \text{K}_2\text{HgFeCy}_4 + \text{KHaCy}_2. \]

The addition of the mercuric salt serves the double purpose of converting the interfering ferrous salt to non-interfering ferric salt, and the generation of the solvent \(\text{KHgCy}_3\).

An investigation of a case of solution fouled by ferrous iron led to the discovery of mercurous potassic cyanide as a silver solvent. The ore in question contained from 2 to 3% ferrous oxide, an interference that could not be removed by preliminary alka-
line washes. New solutions on this ore yielded 80% extraction of the silver. The second use of the solution gave 65% extraction, a third 50%, and a fourth 30%. Further use of the solution continued to give this latter extraction. The solution became heavily charged with ferrocyanides of potassium, zinc, cadmium, and other metals which coated the zinc in the boxes and prevented precipitation. Mercureic chloride was added to the mill-solution, as an experiment, with the idea of changing the ferrocyanide to a ferric salt. The remedy was a success, and the silver extraction was raised to 92%, creating the belief that a more active silver solvent than cyanide of potassium had been formed. Careful laboratory investigation confirmed the belief that the more active solvent was mercuric potassic cyanide.

Prominent features demonstrated by further tests on ore containing silver as argentite, proustite, and pyrargyrite, were as follows:

(1) The chemical equivalents in solution necessary for the reaction

\[ \text{HgCl}_2 + 4\text{KCy} = 2\text{KgCy}_2 + 2\text{KCl} \]

sufficient to make a 0.5% solution \( \text{KgCy}_2 \) applied to silver-gold ore, plus 0.5% slaked lime, gave practically no silver extraction, and 30% gold extraction, demonstrating the necessity of ferrocyanide of potassium or some other reducing agent to prevent the formation of mercuric cyanide and the precipitation of metallic mercury. The gold extracted was probably dissolved by the mercuric potassic cyanide formed.

(2) The same mixture, with 0.2% free \( \text{KgCy}_2 \) in solution, gave 86% silver and no gold extraction, proving the efficiency of a protective reducing agent, and that \( \text{KHgCy}_2 \) is not a solvent for gold.

(3) A mixture in solution of \( \text{KgFeCy}_2 \) and \( \text{HgCl}_2 \), sufficient to make 0.3% \( \text{KHgCy}_2 \) by the equation already given, plus 0.2% free \( \text{KgFeCy}_2 \), plus 0.2% \( \text{KCy} \), gave 85% silver extraction and 80% gold extraction, proving that free \( \text{KCy} \) is necessary for dissolving gold, and strengthening the belief that the reactions previously given for solution of antimonial and of arsenical silver are correct, and proving also that the presence of ferrocyanide of potassium retards the solution of gold. For this reason, in practice ores are first subjected to treatment with plain \( \text{KCy} \) solution.

(4) A 0.5% \( \text{KCy} \) solution applied to the same ore gave 51% silver extraction and 90% gold extraction, proving that arsenical and antimonial silver ores are but slowly, if at all, dissolved by cyanide of potassium, and that a solvent for these is formed by adding mercurous chloride to potassium cyanide solution in the presence of free ferrocyanide of potassium.

(5) A 0.2% \( \text{KCy} \) solution gave 32% silver and 90% gold extraction.

(6) A mixture of \( \text{KgFeCy}_2 \) with either \( \text{HgCl}_2 \) or \( \text{HgCy}_2 \) did not make a silver solvent, negatively showing the probability of the correctness of the reactions given for the formation of mercuric potassic cyanide, when adding mercuric chloride to a solution of cyanide and ferrocyanide of potassium.

(7) Experiments, conditions being same as in third test except that no lime was added, on pulp which had been thoroughly washed with distilled water, gave 43% silver and 90% gold extraction, corroborating belief in the correctness of the reactions given for the solution of arsenical and antimonial silver.
The time of treatment, quantity of solution, and amount of lime, Ca(OH)$_2$, added in each experiment was the same. The tests were repeated several times, and the results given are the averages of all the experiments. The use of mercurous potassium cyanide at the Peregrina 44-ton plant increases the silver extraction approximately 15%. Commercially, the return is $1 for 12 cents.

A careful study of the various base-metal and cyanogen compounds in mill solutions, will enable the chemist to improve extractions and to lower the cost of treatment. Almost invariably the double salts of cyanide of potassium, sodium, and calcium, with zinc, ferric and ferrous iron, are present, and generally the salts of aluminum, magnesium, manganese, and of other base-metals. Ferruous iron combines with cyanide of potassium to form ferrocyanide of potassium, and this forms, with the soluble salts of aluminum, cadmium, zinc, calcium, and ferrous iron, white precipitates, $\text{Al}_2(\text{OH})_2$, $\text{Cd}_2\text{Fe(CN)}_6$, $\text{Zn}_2\text{Fe(CN)}_6$, $\text{K}_2\text{CaFe(CN)}_6$, and $\text{K}_2\text{Fe(CN)}_6$, all of which pass the filter-cloths, or are decanted with the solutions, and collect in the zinc-boxes, coat the shavings, and prevent precipitation. As before mentioned mercurous chloride added to mill solutions changes interfering ferrous to a non-interfering ferric salt, and prevents the formation of aluminum hydrate, ferrocyanide of zinc, cadmium, calcium, iron, and so forth.

A number of methods for determining ferrocyanide of potassium in solution are given in the text books, but I have found none of them accurate. The following method has given good results in practice: to an aliquot part of the solution is added just enough silver nitrate to neutralize the free cyanide of potassium, then mercurous chloride is added to excess, and the iron is determined in the well-washed precipitate. This is done by bringing the precipitate into solution with aqua regia, boiling off the nitric acid, and removing the mercury from solution with $\text{H}_2\text{S}$. After the removal of the excess of $\text{H}_2\text{S}$, nitric acid is added to the solution and the iron is precipitated with ammonia. The process is somewhat tedious but accurate.

In practice mercuric chloride is added to the solution in the proportion of eight to one of ferrous iron as Fe when it is necessary to transpose all ferrocyanide present. Mercureous chloride does not precipitate ferric iron. Aluminum and magnesium salts react as acids, precipitating their hydroxides, $\text{Al(OH)}_3$, and $\text{Mg(OH)}_2$, in the presence of free calcium hydrate, cyanide of calcium being formed:

$\text{Al}_3(\text{SO}_4)_2 + 6\text{KCy} + 3\text{H}_2\text{O} = 3\text{Al(OH)}_3 + 3\text{K}_2\text{SO}_4 + 6\text{HCy}$

$\text{MgSO}_4 + 2\text{KCy} + \text{H}_2\text{O} = \text{MgO} + \text{K}_2\text{SO}_4 + 2\text{HCy}$

$2\text{HCy} + \text{Ca(OH)}_2 = \text{CaCy}_2 + 2\text{H}_2\text{O}$

Manganous salts precipitate manganese cyanide, $\text{MnCy}_4$, which forms with cyanide of potassium the double salt $\text{K}_2\text{MnCy}_4$, decomposed by calcium hydrate, precipitating the hydroxide $\text{Mn(OH)}_2$:

$\text{K}_2\text{MnCy}_4 + 2\text{Ca(OH)}_2 = \text{Mn(OH)}_2 + 2\text{CaCy}_2 + 2\text{KOH}$

Ferro-cyanides of potassium precipitates a white ferrocyanide of manganese which acts similarly to the ferrocyanides before mentioned. The double salt of potassium and manganese is also changed in solution to manganicyanide, with oxidation of a portion of the manganese:

$12\text{K}_2\text{MnCy}_4 + 3\text{O}_2 + 2\text{H}_2\text{O} = 4\text{K}_3\text{MnCy}_{12} + 2\text{MnO}_2(\text{OH})_2$

Ferrocyanides precipitate manganese ferrocyanide, $\text{Mn}_2\text{FeCy}_{12}$. Where silver occurs in any of the forms soluble in cyanide of potassium, calcium hydrate added to excess efficiently overcomes the interference. In the absence of an excess of calcium hydrate, a number of manganese compounds are formed, which obstruct the solution-conduits with complex many-colored manganese precipitates, and at times form manganate and permanganate sufficient to color the mill solutions. Manganic salts rapidly oxidize mercurous potassium cyanide to a mercuric condition, destroying its usefulness as a solvent; consequently it cannot be utilized on ores containing any appreciable amount of manganese.

The only reliable test for available cyanide in the mill solution, is titration with nitrate of silver without the use of the iodide indicator.

A very good method for determining gold and silver in solution is precipitation with cuprous chloride. To an aliquot part of solution is added an excess of cupric sulphate and then hydrochloric acid. After one or two minutes agitation the precipitate is collected on a filter paper, and is run in a crucible for gold and silver in the usual manner. This method was suggested by S. B. Christy, of the University of California, in an article read before the American Institute of Mining Engineers, Vol. 26, 1896. It was afterward published. I think in 1901, by Walter H. Virgoe in a paper read before the Institute of Mining and Metallurgy of London. The method is practically accurate for both gold and silver without the addition of sodium sulphite. A modification of the method is precipitation by adding excess of saturated solution of copper sulphate plus 5% free sulphuric acid. This gives practically perfect precipitation of both gold and silver. Freshly precipitated copper sulphide added to an acidified cyanide solution precipitates both gold and silver completely if the solution does not contain more than 0.1% hydrocyanic acid. The advantage of any of the three methods given is that they may be applied to a large bulk of solution, and the whole operation completed within one hour. An excess of any of the alkaline sulphides completely precipitates silver from the cyanide solution.

The chemistry of the zinc-box is only interesting when mill solution is allowed to foul, a condition incompatible with successful cyaniding. With comparatively clean solution, no troubles are encountered in precipitating silver, excepting from those containing an appreciable amount of copper. In that case, it is advisable to precipitate the copper on a heavy zinc-lead couple (in separate boxes) before precipitating the silver.

**Petroleum** containing 86% carbon has an evaporative power of 18 lb. of water per pound of petroleum.
INEXPENSIVE HOME-MADE 20-TON MILL.

Written for the Mining and Scientific Press
By Theodore Köhnecke.

The mill herein described was built in Central America to treat ore overlooked by former operators as well as the dump-sortings at one of those old abandoned mines known as antigua. Not enough ore was in sight in the mine, which was mostly eaved, to warrant the erection of an expensive modern mill. The plant was originally put in to treat a gross known quantity of only about 2000 tons. In the meantime it was hoped to develop additional orebodies. The total cost of the entire plant, exclusive of superintendence, was $2400, made up as follows: tools and supplies brought from the United States, $650; lumber, $225; labor, $1050; freight, $175; miscellaneous, $300. Labor costs were: skilled labor, $1, and unskilled labor 40 to 50c. per day. Lumber was whip-saved by contract at a cost of $28 per thousand feet. These prices are in terms of United States gold. The mine is situated 65 miles from the coast, and the only communication is by means of pack-mules. This did not prove a great handicap, however, as but little material was brought in.

The site of an old beneficio was chosen in order to use a water-ditch built by the early workers, as well as the foundations for the water-wheel. Gearing, shafting, pinions, and various kinds of iron were obtained from an abandoned pan-amalgamation mill 40 miles away, at little cost beyond that of transportation. A 20 by 4 ft. overshot water-wheel was used to get power for the 16-ft. arrastre. The shafting on the water-wheel was carried out 24 ft. to one side, and a pinion placed on the end which meshes with a gear-wheel on top of the arrastre hub. The gear and pinion were obtained from an old settling-pan. On building the arrastre, a hole 18 ft. diam., with the centre exactly beneath the pinion on the wheel-shaft, was dug 2½ ft. deep. This was filled 1½ ft. high with rocks and mortar, except in the centre, where a post of hard oak 15 in. thick was sunk 3 ft. deep. This foundation sloped slightly from the outside toward the centre. Over the foundation was put a coating of cement, ear being taken to have it water-tight. Next, about 3 in. of dry sand was laid over the cement-floor, and the paving begun. For the paving, flat stones 8 to 10 in. thick were used. These were well wedged, the smaller erratics being tightly fitted with hard-wood wedges. On the outside edge, and against the centre post, the pavement was a little higher than elsewhere. This keeps the pulp beneath the muller. The sand makes it easier to get a level floor, takes the jar off the foundation, and catches anything that comes through the pavement. When the pavement is changed the sand is washed for gold and amalgam, and fresh sand is put in.

The centre post stood up about 8 in. above the floor-level, and was fitted with a step-block from a settling-pan. The hub used was an 18-in. oak-log, with a pin let in the bottom that fitted the step-block, this serving as a pivot. Oak arms, 6 by 6 in., were run through the hub at right angles to each other, and were braed from the end of one to that of the following arm. On top of the hub a gear-wheel was clamped by the spokes to the sides of the log, care being taken to have the gear well centred. A pin similar to that in the bottom of the hub, but longer, was let in the centre. This was caught in boxing from above, and served as a steadier. The gear meshed with the pinion on the water-wheel shaft. To carry the two boxings, two 6 by 8 in. timbers were laid across the arrastre on bents, high enough to clear the gearing. A wall was next built around the edge of the arrastre, 1 ft. thick, and 1½ ft. high, leaving a gap 6 ft. long in front, for the screens. Wooden sills were put in this gap to hold the frames and launders. The bottom of the wall was let into the foundation and the lower inside portion was given a cement-coating to prevent leakage. An 8-ft. copper plate, placed a few inches above the ground, took the pulp from the screen-launders. From the plate the pulp went to three spitzkasten.

While erecting the arastre pine lumber was being framed for three 16-ft. leaching-vats, two 12-ft. settlers, two 8 by 8 by 7 ft. stock-solution vats, a dump vat, and a gold-solution vat. All the vats were square, and, because of the scarcity of stay-rods, barbed wire, doubled several times, was used. The wire was run through holes in strap-iron, and wedges were driven through the loops to tighten the wire. Putting in the pipe-fittings was a difficult piece of work, owing to part of the pipe being old and worn, and as everything had to be cut and threaded by hand, the work was very tedious. From the plates the pulp was run into three spitzkasten, the coarse from these going direct to the leaching-vats, and the overflow to the settling-vats. This slime was stored until such time as it would be practicable to treat it. When once adjusted and in running order, 20 tons daily was crushed and treated. The ore was a granular rock, which broke down quite easily under the muller. Averages of 25 working days per month were made for the first six months, the chief cause of delay being the changing
of muller-stones and pavement blocks. The mullers lasted from two to four weeks, and the pavement from two to three months. Two heavy and two light stones were used as mullers, the former weighing from 1000 to 1400 lb., and the latter from 800 to 1000 lb. The entire plant was installed and running in good shape in five months from the time when construction started. To have built a milling plant of equal capacity would have cost, with freight and construction charges, $20,000, and while a modern mill possibly could have been run at a slightly lower cost per ton of ore treated, and would, of course, last much longer, still it would have to treat a great many thousand tons to make up for the difference in cost. In operation but one man was necessary to look after the arrastre-plant, so that the cost of superintendence was very low for a plant of such limited capacity.

At many mines, where no custom mills are at hand, and where the ore is not available in sufficient quantity to warrant the installation of modern equipment, plants of the type of the arrastre described could be used to advantage. The low initial cost, and the ease of construction, bring them within reach of comparatively poor men. Only ordinary ability and ingenuity are needed to erect a plant of this kind, which will often produce enough to properly equip a mine, when subsequent development shall warrant it.

**BAUXITE.**

The production of bauxite in the United States in 1907, according to the U. S. Geological Survey, amounted to 97,776 long tons, valued at $480,330. This is an increase of 22,444 tons, or almost 30 per cent over the production of the year before, and an increase in value of $112,019, or a little over 30%. The average price of the material at the mines was about $4.91 per long ton, an advance of about 2c. over the returns for 1906. It has recently been claimed that a source of aluminum might be found in India, where thousands of square miles are covered with deposits of alumina laterite. True laterite is essentially a mixture of iron hydrate, aluminum hydrate, and free silica in varying proportions. It is identical in type with bauxite, being merely a ferruginous variety of the latter. By diminution in the iron oxide and corresponding increase in the alumina, laterite merges into bauxite. Between bauxite on the one hand and limonite on the other, all sorts of mixtures may occur. In India laterite is reported as derived in part from rocks in place, as is the ease with our Arkansas bauxite deposits, or as having been transported. The high-level laterites of India are said to bear a striking resemblance to bauxite. The chief uses of bauxite are:

1. As raw material in the production of metallic aluminum, which is by far its most important use. A large part of the output of the State of Arkansas has been devoted to this purpose, and the production from this State has shown remarkable growth during the past few years.

2. In the manufacture of artificial abrasives (alumina).

3. In the manufacture of refractory brick. The last use in refractory brick is of recent date. The bricks are of chief value in resisting the corrosive action of molten metal at high temperatures, and hence are applied in basic open-hearth steel furnaces, in furnaces for refining lead, in copper reverberatory furnaces, and of the linings of rotary portland-cement kilns. In the manufacture of the brick the bauxite is first washed to remove free silica and then calcined at a temperature of 2500°F. Very little or no shrinkage takes place below the temperature of 2390°, hence 2500° is about the lowest safe temperature that may be applied. The calcined material may be bonded with plastic fire clay, sodium silicate, or free lime, and the bricks, after drying, are burned in down-draft kilns at high temperatures, such treatment rendering them hard and tough. A 9 by 2½ by 4½ in. brick, weighing 7½ lb., has been found to stand a crushing test of 10,000 lb. per sq. in. For open-hearth steel furnaces a high alumina and low silica brick is essential, and the purer the alumina, the more satisfactory the results. The pisolites or small rounded conglomerates are found more satisfactory for this purpose, as they carry a higher content of alumina than the other grades of bauxite. This material is obtained by selectling, washing, and sifting the purest bauxite at the mine. The finer material, containing the greater part of the silica, passes through the sieve and is rejected. Recent tests have shown that bricks containing less than 12% silica would be satisfactory, and that in open-hearth steel furnaces they withstand the corrosive action of the metal and basic slag as well as magnesite bricks. The reason for this resistance may be due wholly or in part to the fact observed by Sir William Siemens that bauxite, when subjected to the intense heat of the furnaces, is converted into a solid mass of emery, so hard as to be scarcely affected by steel tools and able to resist mechanical, chemical, and electrical action. As a lining in rotary portland-cement kilns, bauxite bricks are giving satisfaction. They are soft enough to allow a coat of the cement to stick to them and thus protect them, lengthening their term of use, and still not soft enough to allow any part of the bricks to be pulled away. Only a small part of the kiln need be lined with the brick, namely, the hot zone 10 to 12 ft. long in a 60-ft. rotary kiln. The most recent applications of bauxite brick are in the lining of lead-refining and copper reverberatory furnaces. During the process of lead-refining the slag which rises to the surface is composed for the most part of basic oxides which attack the silica in ordinary fire-brick linings. The use of bauxite brick largely composed of basic oxide has reduced the tendency to reaction with consequent increased duration of life to the furnace lining. It has been estimated that bauxite brick lasts five to six times as long as ordinary silicious fire-brick.

---

GEOLOGY OF THE MINING DISTRICTS OF CHIHUAHUA, MEXICO.

Written for the Mining and Scientific Press
By Rufus M. Bagg, Jr.

(Continued From Page 153.)

Geologists visiting Mexico cannot fail to be impressed with the following facts:
First, the remarkable richness and extent of the Mexican ore deposits. Both in Chihuahua and elsewhere this is seen over and over again. For example, there is one quartz vein, the Rosario, in the Guadalupe y Calvo district, which varies from 60 to 150 ft. across, and where measured by Mr. Weed was 110 ft. wide. Again, at the Palmilla mine near Parral the orebody is 20 ft. wide at a depth of 75 ft., 40 ft.

wide at the 400-ft. level, and is said to be 185 ft. in maximum width at the 600-ft. level.

Second, the great distance between the mining centres. This is well illustrated in Monterde. Forty miles west lies Guazapares with its quartz veins; 40 miles north of Monterde lies Urñaúiche, a large and still active camp, producing gold, silver, and some copper; 40 miles east lies Maguariche with its narrow fissure-veins yielding gold and silver. A little farther south lies Urique, one of the oldest and best known gold-silver camps of western Chihuahua. It is a well known fact that in many areas mines occur along mineralized zones which represent lines of structural differences and deformation, but in this case the deposits are in widely separated areas, and on unconnected mountain ranges.

Thirdly, the serious difficulties, chiefly due to lack of transportation facilities, which attend the profit-
able working of many large and important deposits.

The ore deposits of Chihuahua may be broadly grouped into three types:
First, deposits in solution-chambers in sedimentary rocks, chiefly limestone. These are of course of secondary origin, and the minerals are as usual, silver, silver-lead, copper, and zinc.

Second, ore deposits occupying true fissures, usually quartz veins in an igneous matrix.

Third, ore deposits in fault-zones and in zones of shearing.

Deposits in solution chambers constitute a very common type. The Rio Tinto and adjoining mines at Terrazas, 25 miles north of Chihuahua, have yielded considerable copper ore which was taken from chambers filled with chalcopyrite, cuprite, some malachite, and chrysocolla, in a highly fractured limestone, traversed by small intersecting faults, and with the solution-chambers relatively small below the first 100 ft. The characteristic gossan of iron-ore is found here, and has been of service in fluxing the copper-ore which is treated at the mine in two small furnaces. A porphyritic dike, probably of andesite, cuts through the western slope of the hill, and has metamorphosed the limestone along its contact into a massive garnet-rock. A second example of this type is well exemplified by many mines in the long-famous Santa Eulalia camp. This deposit was discovered in 1703, and its mines have been worked for silver and lead almost continuously to the present day. The camp has no water-supply available and
its development has been dependent upon Chihuahua, where two streams, the Chubiscar and the Rio de Dios, were able to furnish water for the reduction of the ores. El Caballo was the first property opened, and this mine, together with the San Marcos, La Vieja, Dolores, and San José, produced those extraordinary treasures which made the region noted at the beginning of the eighteenth century as one of the richest silver districts in the world.† The amount of ore which has been stolen from this camp, together with that which has been illegally mined but never reported for taxes, will of course never be known, but the records show that from 1795, two years after the discovery of the mines, down to 1884 Santa Eulalia yielded 111,590 bars of silver, having a value of $120,634,585. Since 1884 the mines have been producing much more heavily, and the present monthly shipments to El Paso are approximately 20,000 tons of ores of silver, silver-lead, and zinc.

Solution-deposits are also finely developed in the Cerro de Almoloya. This mountain lies between Jimenez and Parral, on the Mexican Central railroad, nine miles south of the little station of Baca on the Parral branch. It is an outlier of Mesozoic (Cretaceous?) limestone, about ten miles long, three or four wide, and stands 1000 ft. above the surrounding plain. The limestone is of two types, one blue and the other gray or white, and the solution-chambers occur in both series. The ores are found principally on the lower north slope and also high up on the mountain-side. There is also a gold mine on the southwest slope. The ores carry silver, copper, zinc, and gold, and all producing mines are situated within a radius of three miles or less. The zinc mine lies above and to the south of the great Cigarrero copper-silver property, and has chambers of ore from 10 to 20 ft. wide, filled with solid smithsonite. Some of the ore is beautifully straticulate vertically and carries occasional bunches of pale green anuri-calcite, a rare copper-zinc mineral. On the crest of the mountain the limestone is thickly bored full of holes extending downward to unknown depths in the limestone. These holes vary in size from an inch to a foot or more in diameter. They are supposed to be the lines of ancient drainage connected with the solution-chambers. Fault-planes are pronounced, and have been a further aid in the mineralization of the limestone.

Deposits in fissures are very plentiful in the Chihuahua mountains. In this class are included only the vein-deposits occupying original fissures without subsequent movement. There is another group of faulted fissures which have had a double origin, and the majority of the mines in these belong to the third group. Most of the pronounced fissure-veins, however, show some evidence of movement either as horizontal shear or as vertical thrust, since they are the lines of greatest weakness in the rock-mass where they exist. In a highly mineralized region where fissure-veins are abundant, as, for example, at Ocampo (Jesus Maria), some of the fissure-veins are undisturbed, with their quartz vein-filling ‘frozen’ tightly to the country rock, while other veins not far distant may be greatly faulted. The La Cruz mine, six miles west of Ocampo, is an example of a faulted fissure, belonging, therefore, to the third class. Here the condition is more complicated than usual, owing to the intrusion of an andesite dike 28 ft. wide, and highly impregnated throughout its entire width with minute crystals of dodecahedral and cubic pyrite. Slight movements along a fissure-vein will more readily develop alickeinds on the lower or foot-wall side than on the hanging-wall side. It is certainly true that in a number of deposits in Chihuahua belonging to this class, the hanging-wall side is more irregular, more frequently frozen to the country rock, and the ore is of lower grade than in the foot-wall side. The La República mine, southwest of Sahuyascan, has a solid quartz vein 6 ft. wide in all its workings, averaging 110 oz. silver per ton (no gold) that is highly mineralized with ruby silver and other silver sulphides throughout its quartz vein-filling. The vein dips sharply under the creek in which the mine occurs and on its foot-wall often carries seams of native silver, evidently a result of precipitation from the original sulpho-salts.

The mining centres in and around Ocampo afford many excellent examples of true fissure-veins. The camp was discovered in 1821 when the San Antonio mine was opened. Some of the more important mines are the Santa Juliana, which has produced upward of $100,000,000; the Santa Edwigeis, which in seven years, 1838-1845, had a production record of $5,000,000; and the Wattersen gold mine, which is still producing about 100 tons of high-grade gold ore daily. The Conchofino mine, six miles north by east, has a 60-stamp mill, and has been producing upward of half a million annually. It has now been taken over by the Greene Gold-Silver Co., and will be worked on a larger scale. This vein is pronounced and its orebodies are wide, though the ore is low-grade. The workings have reached a depth of 1000 ft. The country rock, in addition to sedimentaries, around Ocampo and Conchofino consists of rhyolite, andesite, diabase, volcanic breccia, and rhyolite tuff. All are highly silicious, and the vein-filling is invariably quartz, carrying both gold and silver. The veins have in many instances been worked to water-level, and the old workings still exist with their walls running up the mountain side, while the lower portions are being uncovered and developed by American capital.

Similar fissure-veins occur at Sahuyacán and at El Pilár, two days’ journey by mule-back west of Ocampo. Two sharp volcanic cones, apparently rhyolite, rise here to great height, the most imposing of which, El Pilár, having upon its base the mining camp of Socorro. Both these buttes represent volcanic necks from which radiate many fissure-veins, quite narrow but of great length, and yielding high assay-values in both silver and gold. The gold is frequently visible to the naked eye, while the silver is usually in the form of pyrrargyrite, proustite, and the brittle silver, stephanite. More rarely the simple sulphide, argentite, is found.

Ore deposits in fault and shear-zones are developed

in zones where the fracturing is pronounced and the movement extensive. Such deposits have the following characteristics in Chihuahua: (1) The ore is developed in elongated irregular lenses or pockets, separated by lean or barren portions. The amount of disturbance which the magma has suffered since fracture took place has a direct relation to the irregularity, extent, and amount of ore present. (2) There are certain zones of enrichment in such deposits, and these are sometimes developed in the wider part of the vein instead of at its narrower portions. (3) Such deposits are not all developed vertically downward, but pitch in a given direction, and since such ores are irregular it is often necessary to sink on wide lenses, and to cross-cut at close intervals in order to thoroughly explore all the mineral ground along the faulted area. The widest orebodies are of course typically developed where the vertical disturbance has been accentuated by horizontal shear.

The best illustrations of this type of deposit are seen in the La Reina mine, seven miles south of Cusihuiriaèchi. The vein trending northeast-southwest has been sheared and slickensided on an extensive scale. It is from 6 to 20 ft. wide and is opened to a depth of about 400 ft. It is producing about $20,000 per month. On the lowest level a branch from the main vein extends in a long curve away from and then toward the big vein, and is apparently separated from this by an immense 'horse,' several hundred feet long. It is about two feet wide and carries large amounts of silver chloride and bromide.

Five miles east of the Sinaloa boundary, in the extreme southwest part of the State is another example of this type of deposit in the Lluvia de Oro mine, which has been lately described by R. H. Burrows. He states: "The orebodies occur in a bed of limestone which outcrops as a bold cliff along the east face of the ridge, and which has suffered extreme faulting and fracturing, the mineralized area having been mineralized about 2500 ft. by the intrusion of a body of diabase, the latter now forming the underlying rock of the district."

The following section is given: 250 ft. massive gray limestone, marmorized; 20 ft. fissiliferous limestone with Rhyochonella laccinosa, Belfemites, and other fossils determined to be of Jurassic age: 300 ft. thin-bedded limestone, passing into mixed slate and limestone beneath: 100 ft. sandstone, or tuffs, at base in thin beds, the total thickness being 670 ft. Below this is about 4000 ft. of diabase resting upon granite. According to Mr. Burrows this is a metasomatic deposit of quartz within the limestone where the ore consists of gray quartz, rusty with decomposed iron pyrite and carrying on an average 3 oz. gold and 30 oz. silver per ton throughout its lower portion. No description of the Chihuahua mines should omit the Batopilas silver deposit in the south-central portion of the Sierra region. This old silver mine has had a long and interesting history. As early as 1632 silver was taken from this camp, the first mine opened being known as La Nevada. This is the camp mentioned by Von Humboldt, who says that masses of pure silver weighing upward of 200 kg. were extracted from it. The rock is described as a diabase, and the ore is supposed to be due to faulting. A large number of prominent producers are omitted from this paper. Space will not permit an attempt to even catalogue the producing mines of the State. An attempt is now being made by Mr. Griggs of Chihuahua, who has charge of the State Mineral Exhibit in that city, to prepare such a catalogue.

It is doubtful if there is any region in the world, with an area of equal extent, that can exceed the State of Chihuahua for its mineral resources. To these should be added the great timber and agricultural possibilities. The cattle ranches are among the important assets of the State. The traveler en route to Miñaen passes the ranch of the late Don Carlos Zuloaga, which is reported to have had 99,000 head of cattle upon it in 1900. It is impossible to estimate the wealth of Chihuahua. This is due in part to the undeveloped condition of the mining industry which, notwithstanding the former immensity of ore production, is yet only in a development stage. The next ten years will show a marvelous increase in gold, silver, zinc, lead, and copper production. The completion of the Kansas City, Mexico & Orient railroad will make possible the economic working of hundreds of deserted mines.

ORE-SHOOTS AT BUTTE, MONTANA.

By Reno H. Sales.

The subject of 'ore-shoots' or 'bonanzas' or whatever we choose to call the localized occurrences of relatively richer bodies in a vein or ore deposit, is one of the most perplexing and one of the least understood of all problems relating to the geology of metaliferous deposits. Their importance in mine sampling and mine valuation, is familiar to all who have had occasion to study closely veins of the ordinary type. The presence of well-defined ore-shoots in the copper veins of the Butte district was not recognized in the earlier history of the camp; and it appears that they were of doubtful existence as late as the year 1897, when the Butte Special Folio was issued by the United States Geological Survey. This may be accounted for in large measure by the fact that most of the earlier mining operations were upon what are known as the older 'East-West,' or 'quartz-pyrite' veins, which are of remarkable width and uniformity in mineralogical character. The more prominent of these have been staked for hundreds or even thousands of feet continuously along their strike, showing little, if any, disposition to develop shoots. There is, of course, a considerable variation in content of the valuable metals in different parts of the veins, but such may not be properly designated as shoots. Later developments, however, have brought new facts to light, and in at least two vein systems which are known to be younger geologically than the Anaconda or East-West system, the occurrence of ore in large irregular bodies, is a characteristic feature. These later veins have been termed fault veins, because they are known to cut and displace the earlier veins, and because of their physical character. They consist mainly of crushed country which may be either granite, aplite, or quartz-porphyry, carrying small amounts of quartz and iron pyrite either as finely disseminated material, or in the form of small stringers or scarf-like masses irregularly scattered through the crushed country. The fault, or crushed zone, is usually narrow, varying in width from five to twenty feet, exhibiting one or more well-defined planes of movement marked by a dark blue or black tough clay one-quarter inch to five or six inches thick. The above description applies to the barren stretches of vein between the ore-shoots.

Some of these fault veins have been opened up on the strike for more than a mile, and at intervals immense ore-shoots have been uncovered. These ore-shoots, which are quite irregular in form, show great variations in size, from mere bunches or pockets, up to great ore-bodies over 1000 ft. long, and of unknown height, in some instances 1500 to 2000 ft. vertical height having been developed with no bottom yet known. The thickness of the ore varies from nothing up to 20 ft., or the entire width of the fault-zone. In the latter case, there may be a complete replacement of the crushed country by ore minerals, leaving little evidence of the faulted character of the original space.

The mineralogical content of these shoots is chiefly quartz and iron pyrite, with smaller amounts of zinc blende and copper minerals, namely, chalcopyrite, enargite, bornite, covellite, and chalcocite, the last named being here of rare occurrence. There seems to be no method of reasoning to foretell the position or extent of these shoots. They usually fade out on the strike within a distance of 50 ft. or less; although the limiting boundaries are not always well marked. There appears to be no regularity to the pitch of the shoots, that is, there is no common direction of pitch. There are many examples of what might be termed 'shoots within a shoot,' or localized areas of rich ore within the main orebody as above outlined. There are also enrichments within the larger shoot due to mineralization along cross-faults which are only local and do not extend beyond the boundaries or walls of the main fault. I have observed many examples of this character, indicating continued movement, or readjustment of the orebody, within the fault-zone during the period of vein-forming action. Such internal transverse fissures may be filled by richer ore, or there may be an enrichment of the earlier formed ore adjacent to the fractures, or both conditions may be present. Longitudinal fissuring has occurred during the period of mineralization, and has had an important influence upon the nature of the orebody, but these effects are not readily determinable, as the age of such fissuring is not generally evident.

The conditions under which these ore-shoots were formed are somewhat obscure, and no attempt will be made at this time to enter into a discussion as to their genesis with reference to their mineral content, that is, whether the ores, either wholly or in part, were deposited from ascending or descending solutions, traversing the fault fissure. A few observations regarding the extent to which the large fault fissures in the Butte district have acted as channels or passage-ways for underground mineral-bearing solutions, may be of interest. In the first place, it is evident from the thoroughly altered condition of the crushed granite at all points along these faults, that there must have been, at an early period, a reasonably free circulation of waters throughout the entire extent of the fault-zone, producing this intense alteration. But, as these fault-zones are explored by mine-workings, long distances along the strike are found to be absolutely dry and barren of ore, while the ore-shoots themselves are usually wet. These facts indicate that the present positions of the shoots represent the channels or zones through which the ore-bearing solutions traveled. The concentration of all the solutions traversing the fault into these channels, I believe to have been brought about through the development, by continuous earth movements within the fault-planes, of impervious barriers composed of altered, clayey, crushed granite and attrition-clay or gouge. The presence of this impervious material directed the circulating waters along the lines of least resistance. In other words, solutions which at first traversed the entire extent of the fault fissure, were corralled, so to speak, and confined to

*Abstracted from *Economic Geology, Vol. III, No. 6, June-July 1908.*
more definite zones, while the walled-off or excluded portions gradually became dry. The location of the ore-shoots was therefore determined, in part at least, by the physical nature of the country composing the fault-zone. The size and richness of the orebodies may have been influenced to some degree by the cutting off, or damming back, of the mineral solutions, through the later development of impervious material along or within the fault-zone. I have seen many examples of this phenomenon in various parts of the Butte district where the clay and crushed granite of a fault acted exactly as a dam, holding back enormous quantities of water. On the 1000-ft. level of the Six O’clock shaft a cross-cut was driven for several hundred feet, directly under the foot-wall of a large fault zone, in an absolutely dry unaltered granite. After passing through the thick clay and crushed granite foot-wall, a perfect reservoir of water was encountered, the whole mass of fractured rocks for a hundred feet or more being thoroughly saturated. A condition exactly similar was noted on the 1100-ft. level of the Butte & London mine. Alternate wet and dry areas along faults in Butte are characteristic. The wet zones often encountered when drifts intersect faults are usually due to the presence of shattered granite or vein near the fault, and not necessarily from the water traversing the fault-fissure itself.

That the immense quartz-pyrite veins of the old East-West system of copper-veins in Butte were formed along shear-zones having but slight displacement, I have no doubt. Repeated observations show that these earlier fissures intersect the quartz-porphyry dikes, and hence are later. The wonderful continuity and uniformity in size and character of these veins are due to the significant fact that they were not formed along fissures of extensive movement, such as I have described above, but were fracture-zones along which there was insufficient movement to develop the impervious fault-material so characteristic of larger faults. A free general circulation was thus permitted throughout the entire extent of the fracture-zones, finally producing extensive quartz-pyrite veins, of which the Anaconda and Syndicate lodes are the best examples. Later cross-faulting has cut and displaced the fault-veins above described, also the veins of the Anaconda or East-West system, resulting often in an enrichment of the fractured veins adjacent to the intersecting fissures.

The circulation of underground waters through fault fissures of the character above described does not appear to have been in this district as free and extensive as is generally supposed. During the period of faulting, there was more or less fracturing of the older veins, together with strike-faulting along them. The passages for the circulation of mineralizing solutions thus afforded in and along these older veins, were far more important and contain more ore than the main fault-fissures themselves.

Bearings of belt conveyors should not be lubricated with oil, because it will almost surely leak out and coat the face of the pulleys and thus cause slipping. A heavy grease or graphite should be employed.

Steam Scraper for Placer Mining.

Written for the MINING AND SCIENTIFIC PRESS

By H. W. Turner.

S. J. Norris, of Oroville, California, has introduced a new method of handling gravel. This is a steel-scraping machine with a total capacity of about six cubic yards which fills itself as it is drawn forward over the placer deposit, and is then hauled by wire-cable up to the sluice-way and dumped into the sluices or other gold-saving device. The power is furnished by a donkey-engine of 130 effective horse-power, wood being used for fuel. In the case illustrated by the accompanying cut the scraper is operating on Coquett creek in Plumas county, California, on creek gravels. The donkey-engine is placed on the slope about 70 ft. vertically above the gravel, and the sluice-way is placed perhaps 30 ft. below the engine. The scraper operates fairly well, but it is evident that it would handle more gravel if working on placer-material lying on gentle slopes or in sloping basins in ravines. In this case the best location for the engine would presumably be at the bottom of the slope, the sluice-way being above the engine. The pull of the loaded scraper would then be down-grade to the sluice-way. There are slope and basin-deposits in places in the Sierra Nevada. The gold-bearing material often consists of soil and detritus enriched by local stringers and, with a minor amount of water-worn gravel, lies above the ditches, and hence cannot be sluiced in place. There would thus seem to be a field for the use of such a steam scraper, which is not filled by any other device.

Carmen Island, in the Gulf of California, 100 miles south of Guaymas, Mexico, and 17 miles long by 5½ miles wide is an almost solid deposit of salt. At present 1200 tons of salt per month are being taken out on not more than 200 acres in area. It costs about 50c. per ton to mine and deliver to a vessel. The product is marketed along the west shore ports. It is not refined.

In a gas explosion at the Rikovskaya mine, near Yusovo, European Russia, July 2, 300 men are reported dead; 214 bodies have already been recovered. A fire has broken out and is working toward the inner galleries, where it is said that 150 men are still alive but imprisoned, and in spite of their audible cries for help, cannot be reached by rescuers.
WORKING COSTS IN MINES, AS PRACTISED ON THE RAND.

By John A. Dennison.

*Mining is essentially a commercial business, and therefore should be conducted on lines which approximate as closely as possible to the recognized forms of established businesses.

Accounts are kept for four principal reasons. First, for the convenience of the manager of the mine, who naturally has to follow the cost of each department closely; second, to enable consulting engineers and controlling firms to see the cost of each branch of work, both on the surface and underground, with a view to cheapening or improving such work; third, to supply Government with statistics; fourth, to enable the mine-owner or share-holder to see how his business is progressing, the amount of profit made, or the dividend he is likely to receive.

All initial expenditure on machinery and plant, buildings, dams, shafts, development, head-gear, and the like, up to the time of crushing is, of course, capital expenditure. Any surplus working-capital that there might be would soon be spent in completing the plant, and in improvements. The trouble arises after the plant starts producing, when all the working capital is exhausted, how to deal with the further expenditure on similar items which goes on more or less during all the life of the mine, that is, whether to charge it to capital-account or to working-costs. If the items are large (duplication of mill, new vertical shaft, new cyanide or slime plant), and the necessary money is raised by a new issue of shares, debentures, or special loan, such expenditure is generally considered capital expenditure. But if the items are smaller ones occurring and recurring during the life of the mine, are paid out of the profits, the mine-owner or share-holder will, so far as he is concerned, consider them working costs. The ideal method, and perhaps the simplest, is to close the capital-account when the plant is complete and running and the original working capital is exhausted; and not to re-open it except for special expenditure of money specially raised.

Working-costs naturally vary in different countries, on different fields, and also on the same fields; in the latter case, owing to relative size of plant, hardness of rock, and dip and thickness of vein. But many managers are more or less driven by the directors or the public to show low working-costs, as it is unfortunately often considered that low working-costs mean good management, whereas they may often mean poor policy, and slightly higher costs might result in additional net profit.

Looking at a mine again as a commercial business, it seems necessary or advisable that working-costs should in some way reflect the amount of capital expended, either through depreciation or interest and redemption of loans. The prevalent practice, however, seems to be not to include depreciation in working-costs, even when it is allowed for, but to write it off as 'premium on shares' account, or some other equally useful account, so that it does not directly show in the costs. The consequence of the usual practice of making no allowance for depreciation or redemption of capital in mine-costs is that it is often impossible to see how much real profit is being made; in fact, in cases where working-capital shares have been issued at a premium the profits or dividends often seem large on the nominal capital, but would be much smaller on the total amount of money raised for working capital, and still smaller if on the total amount spent, including capital expenditure out of profits, which in time may amount to large sums. Sometimes, indeed, if the whole expenditure were considered, the profit shown would not be sufficient to redeem the capital, much less pay interest on it. Curiously enough, money spent on capital-account is often not looked upon as additional working-capital raised. Interest on and redemption of such money must be allowed for before the additional plant can be correctly said to have produced any additional profit.

Capital expenditure on the Rand may be divided into two groups: (1) initial expenditure to bring a mine to the producing stage; (2) subsequent expenditure. The initial expenditure may be divided into four headings: (a) Property account; no depreciation is allowed for this in the balance sheets or working-costs, and it stands at its original cost entirely through the limited life of the mine, though the exhaustion of ore makes it lose and less valuable. (b) Machinery and plant, buildings, and dams; in some cases depreciation is written off every year to premium on shares account, or appropriation account, in other cases not at all, it being considered that as the money has been spent in bringing the mine to the producing stage, depreciation of the account would mean the creation of a cash reserve and payment of smaller dividends, if it had to be debited to profit and loss account. (c) Shafts; all initial expenditure on vertical and inclined shafts is left as an asset in the balance sheet, that is, neither depreciated nor redeemed. (d) Development; in the largest group of mines initial expenditure on development, that is, sufficient to bring the mine to the producing stage, is not written off, depreciated, or redeemed at all, it being decided to keep ore reserves to this or a higher level by current development, which is charged direct to working costs.

Regarding subsequent capital expenditure, that is, after the milling stage is reached, there are many methods employed, and each mine-management has its own ideas as to what constitutes capital expenditure. Any new expensive machinery, increase of plant or buildings, or new shaft, is charged to capital account, all repairs and renewals being charged to working-costs. Sometimes a manager is given a stipulated allowance for renewals of machinery and plant, and he has to make this sum do. Some mines on the Rand have at times closed the capital accounts altogether, all further expenditure being charged to working-costs; but most of them have at later dates re-opened the capital account for various reasons. The chief trouble is in regard to inclined-shaft sink-
ing, cutting stations, driving, winzing, raising, crosscutting, box-holing, and so forth. In one large group of mines all such expenditure is called development and is charged to working-costs monthly, care being taken to spend as far as possible an equal sum every month sufficient to keep the ore-reserves up to a fixed standard (2 to 3 years ahead of the plant), and generally to increase the total tonnage gradually. This system deserves consideration, as it is the simplest, and gives the shareholder the clearest idea of the position. Another favorite system on the Rand is to consider all current sinking of inclined shafts, cutting stations, and sometimes main cross-cuts, as capital expenditure, and not as development. In such cases only the costs of driving, winzing, raising, and box-holing are considered to be development, and these are debited to a separate capital account, which is practically a suspense account.

As regards additions and renewals to machinery and plant, beyond ordinary maintenance, after the initial plant is completed, the system adopted should depend upon whether the money is provided out of profits or raised separately. If raised by means of an issue of shares, it would doubtless be considered capital expenditure, and in some cases depreciation would be charged somewhere in the balance sheet or appropriation account, but, according to present practice, would not show in working costs. If the money is raised by an issue of debentures or a loan, under the present system the interest is sometimes charged to working costs, but generally to an appropriation account, and the redemption of the debentures or loan is not shown in working costs. The result of this system is that capital expenditure goes on year after year, especially in directions that will show any decrease in working-costs; the decrease generally follows, but as the costs contain no portion of the extra expenditure it is almost impossible to tell whether the saving in costs has been sufficient for the interest and redemption of the additional expenditure. Personally, I think the system of a monthly allowance in working-costs for additions to plant and machinery is in most cases the best, provided this allowance is used as a fund which is only overdrawn in exceptional cases. If by this means the plant is maintained at full value there would not appear to be the same necessity for depreciation.

Depreciation on original machinery, plant, buildings, and equipment is a vexed question. Generally speaking, companies whose head offices are in London are compelled by their auditors to write something off annually for this, but it is rarely shown in working-costs. Companies with head offices in the Transvaal and elsewhere do more as they like, and frequently no depreciation is written off.

Stores on Hand: This item in the balance sheet should include only such stores and duplicates as are suitable for current requirements. All accumulations of discarded appliances or deteriorated stores should be written off every few months, the loss being charged to working-costs in average monthly instalments.

Suspense Accounts: A few mines manage to do without these accounts (which are never disclosed in the monthly or quarterly reports issued to shareholders, and are very rarely disclosed clearly in annual reports), but in general they seem to be regarded as necessary evils, and at times they are almost unavoidable. Annual payments for fire insurance and licenses, as well as recruiting fees for native labor, and the like, are charged to suspense accounts, and working-costs debited monthly with a proportion.

Gold Reserves: Most of the Transvaal mines have kept a certain amount of undeclared gold in reserve during the past few years with a view to showing regular outputs; at times these reserves have amounted to as much as 10,000 or 20,000 oz., not kept at the mine, but realized by the bank in the ordinary way, credited to the general account, and in many cases the money has been spent. The legality of such a course has been questioned, and some mines have now abolished the system; others continue it, but publish the position of the reserve at the same time as the monthly or quarterly profit; and a few retain the original system of undeclared gold-reserves.

Head-office charges are sometimes included in working costs where the head-office is near the mine, say in Johannesburg; in other cases they are not so included. This is a frequent cause of difference in working-costs. Sometimes the expenses of management, salaries of manager and consulting engineer are included in general charges under working-costs; sometimes they are given separately.

Realization of Gold: On the Rand this item of cost is frequently debited to gold account, the net yield only being shown in monthly and annual reports, thus showing the lowest possible working-costs. In many other cases it is charged as a separate item or under general charges to working-costs; and in one case it is deducted from the yield in monthly reports and included in working-costs in the annual report.

Causes of accidents in the mines of the Rand for the year ending June 30, 1907, are distributed as follows, according to a report of the Government mining engineer, published in The South African Mining Journal.

Owing to danger inherent to work itself...55.07 %
Through fault of fellow-workmen........ 8.97 %
Through carelessness or ignorance of injured persons ..............................33.94 %
Owing to defective plant or material...... 2.02 %

In other words, practically 43% of the casualties which occurred are directly attributable to either the carelessness or ignorance of the persons employed underground, while a very small proportion of the accidents are in consequence of defective plant or material. The majority of the former class of accidents are due to the colored laborers, which fact is a strong argument in favor of their more efficient training. Our Transvaal contemporary suggests that this would be accomplished if the natives were engaged on longer contracts, perhaps three years, instead of on the very short terms, 4 to 12 months, as is the custom at present.
CONTINUOUS SLIME FILTER.

Written for the Mining and Scientific Press
By Robert Schorr.

Your journal has given the subject of filter-pressing slime more thorough and strictly professional attention than any other publication. It is obvious that most of the space has been devoted to discussion, and to illustrations of those vacuum and pressure-filters which have proved successful in actual practice. Among the several untried designs which have found due consideration, is also Bertram Hunt’s continuous slime-filtering machine. The stationary type of this appliance has been clearly outlined in Lochiel M. King’s able article, ‘Cyanidation in Nevada,’ of January 25, 1908. This machine is of special interest, as it is apparently the only slime-filter which employs sand as a filtering-medium. For that reason expressions of opinion and data would be greatly appreciated from Mr. Hunt and from all those who have made tests with sand as a filter-bed for slime, and for mixed slime and sand. I do not venture an opinion myself, as I have had no experience in the operation of slime-filters. They have, however, interested me greatly, and about 18 months ago I designed a continuously-acting filter-wheel, patents for which were granted recently.

The main object of this design was to create a filtering and washing apparatus which would be entirely automatic in its operation. Slime transfeets are entirely eliminated, and consequently the time of treatment is reduced materially. In looking over the accompanying drawings it will be realized that a large filter-area can be accommodated upon a limited floor-space. No storage vats, and but little attention and power, are required. Two cast-iron pump-chambers (1) anchored to the sides of a wooden box (2) are the supports and trunions on which the filter wheel revolves. The wheel itself consists of three circular discs (3), thoroughly tied together by steel rods (4). These discs have grooves formed by cleats (5) for the support of filter frames (6) in a position tangential to a circle of a diameter smaller than the wheels. The filter frame can be made either of standard pipe, of cast-iron or wood with filter-cloth, preferably canvas sewed around the same.

The space between the two sheets can be filled in with matting or other porous material. Both sides of each filter leaf form effective filtering surfaces. Each frame is connected by means of pipes (7) to an iron ring (8) revolving with the wheel upon the pump chamber. Local openings in these bring the filter-frames, in the course of one revolution, into communication with the various pumps or other devices for the production of a vacuum for the purpose of withdrawing solution and wash-water, and

Schorr’s Continuous Slime-Filter. Transverse Section.
for forcing off the filtered cakes of tailing by means of water or compressed air.

Corresponding with these three functions, namely, with the formation of cakes by sucking off solution, with the washing of the cakes and withdrawal of the wash-water, and with the discharging of the washed cakes by forcing them off, there are three subdivisions in each pump-chamber. These three spaces, 9, 10, and 11, are connected individually to the necessary apparatus. The tailing falls into a launder (12), and is carried away either mechanically or with water. Various means may be used to revolve the filter-wheel. That shown in the transverse section is probably the most simple, consisting of an ordinary adjustable ratchet (13) operated from an eccentric (14). The gearing and pulley indicated are necessary in view of the slow speed required.

In operation the slime enters the box below the driving-shaft and the level is kept as high as the tailing launder. During the slow travel of the filter-leaves through the pulp the cakes are formed, all solid matter being drawn by the vacuum to the filter cloth. By changing the speed of the wheel the thickness of the cakes can be regulated. During this period each filter is in connection with chamber 9, and the strong solution is obtained separately. The filter planes emerging from the box are subjected to a long water-wash, and the liquor is drawn off through chamber 10 by another pump. From the point where the filter-planes begin to slant toward the tailing-launder they communicate with the central space (11) of the chamber, which is connected to water under pressure or to a compressed-air main. In this manner the cakes are forced off into the tailing-launder for further disposition. Ample time is given for discharging, after which the operation is repeated.

The arrangement, as outlined, may be modified in different ways to suit the material under treatment. The filter-wheel can be housed in a steel shell, with an opening at the highest point for feeding the pulp to the machine. After applying a vacuum or pressure for some time, a door, placed at the lowest point of the steel housing, is opened to discharge the filtered material. Another variation of the design is effected by introducing the material to be filtered through the central shaft of the wheel.

Registration of mining companies in Great Britain, during the 25 years ending with 1904, was at the average rate of one company per day, with an average nominal capital of more than £100,000 each.
MINE REPORTS.

LA ROSE MINES, LTD., COBALT, ONTARIO.

The La Rose mines comprise a group of claims in Cole-
man township, Ontario, aggregating 223½ acres. In addi-
tion the company owns 90% of the University J. B. claims 
of 56 acres. The La Rose mines began operations in July 
1904, since which time, up to June 1, 1908, the gross ore-
sales have amounted to $1,541,519, and the costs have been:

Mining and developing .................. $285,442
Marketing ores ................................ 98,332
All other expenses .......................... 151,904

Total ...................................... $535,478

Thus the Company has earned a net profit of $1,006,041, 
which has been distributed among the stockholders. The total 
tonnage of ore on which this profit was realized was 5583, 
yielding 2,675,161 oz. silver. On the “J. S.” claim, 
fifteen veins have been found, of which only three have 
developed. The main vein has been explored under-
ground to a depth of 240 ft., and for a length of 900 ft. on 
the strike, and very little sinking has been done, as the ore 
production to date would indicate. In connection with a 
geological report on this property, Willet G. Miller, Provin-
cial Geologist of Ontario, presents the general geology of 
the district, including the La Rose mines, in the following 
succinct description:

The geology of the Cobalt area has been described by 
two geologists, and prospectors published by the Bureau of Mines of the 
Province of Ontario. There are three series of rocks in 
the area which have a bearing on the ore deposits. The rocks 
are all of pre-Cambrian age. To the eldest series is 
given the name Keewatin. It is an igneous complex, and 
consists for the most part of greenstones and other basic 
rocks with which are associated in minor quantities acidic 
types such as granite-porphyry and related rocks. These 
Keewatin rocks are described as occurring at one thousand 
in this part of the continent, and were worn into hills and 
valleys much like those of the present surface. After 
the erosion of the surface of the Keewatin there was a subsi-
dence of the land surface, and the Keewatin became cov-
ered with fragmental material which was laid down chiefly 
through the agency of water. This fragmental material 
consisted of gravel and boulders, thrown into sand, sand, 
and sand. The gravel, boulders, and sandstones filled in 
the valleys and other depressions of the Keewatin surface and 
ultimately, probably, covered the ancient hilltops. Through 
the action of various agencies the fragmental material be-
came consolidated and is now represented by what is known 
as the Huronian conglomerate, gray-wacke slate, and so forth. 
It will be seen from what has been said that both 
Keewatin and Huronian rocks have affected the region. It 
will also be clear that the Huronian fragmental material (conglomer-
ate mainly) has a greater thickness at some points than at 
others. Where old valleys have been filled by it the 
thickness may be several hundred feet, while surrounding 
old hilltops the thickness is much less. The third series 
of rocks in the area which is of economic value, is what is 
known as the diabase. This represents basic material 
which intruded both the Keewatin and the Huronian series 
after the close of the Lower Huronian period. For the 
most part, the diabase spread out between the Huronian 
and Keewatin in the form of great sheets of laccolithic 
masses. Since the eruption of the diabase, the area has 
been subjected to great denudation. The surface has been 
cut into hills and valleys and the geological map shows a 
patchwork of Keewatin, Huronian, and diabase, together 
with glacial and recent deposits.

Having briefly described the rocks of the area, the origin 
and nature of the orebodies may be dealt with, details of 
which will be found in the Government reports referred to. 
Immediately preceding the eruption of the diabase, the 
rocks of the area were subject to a great disturbance, 
giving rise to subterranean forces which in the later 
hills and masses the diabase was made to rise upward. After this great distur-
ance, and as the great intruded sheets and masses of the 
diabase gradually cooled, and the surrounding rocks settled 
down through the contraction of the diabase, numerous 
cracks and fissures were formed, not only in the Keewatin 
and Huronian, but also in the diabase itself. It is these 
cracks and fissures which are now occupied by the ore-
"bodies. In all parts of the world we have evidence that 
heated impure waters circulate through the crust after the 
eruption of material such as that of the diabase, to which 
reference is made. In the Cobalt area, such heated impure 
waters, under great pressure and heavily charged with 
mineral matter, worked their way from subterranean 
depths through cracks and fissures toward the surface. 
These waters happened to be charged with cobalt, nickel, 
arsenides and sulphydrates, and, when they approached 
the surface, and had their temperature and pressure lowered, were gradually, and gave rise to the mineral now found in the veins of the Cobalt area. The first minerals to be deposited were the cobalt-nickel 
arsenides (maltite, niccolite, and so forth), together with 
other compounds. The silver minerals appear to have been 
 deposited at a somewhat later period, after which there had 
been another comparatively slight disturbance in the district.

ST. JOHN DEL REY MINING CO., LTD.

Morro Velho, Minas Geraes, Brazil.

The net profit obtained by the St. John Del Rey Mining Co. for the year was £70,440, as compared with an average of £58,747 in the six preceding years. The output for the period was 156,494 tons—156,494 tons—of which 82% were ore, as compared with 85% of the ore treated during the past year. The ore treated 
during the past year was 151,454 tons and the assay value was 
46s. 6d. During the six years from 1901 onward the 
average recovery has been 85%, but last year's figure was 
91%, which made a great difference in the profit, as the 
recovery has been 42s. 4d. per ton, as against the previous 
six years' average of 35s. 6d. This increase in the profit 
is due to a number of causes connected with the redu-
duction department. One was the introduction of tube-
 mills, which has enabled them to stamp more ore, and this 
has enabled the cyanide process to deal with a very large 
percentage for a pyritic ore, which contained 49 to 50% of 
it's gold in pyrite. Exchange in the past year has been a 
triple over 1s. 3d. per milreis, against 1s. 1d. for the 
previous six years.

The cost for the past year was 32c. 10d. per ton, against 
the average for the preceding six years of 33c. 2d., but the 
increased cost of the milreis must be borne in mind. As 
reserves, Superintendent Chalmers reports 1,000,000 tons—900,000 below horizon 11 and 100,000 tons above. In the reserve mentioned was included horizon 15. In horizon 
15 a level had been driven 50 ft. above the true level, and 
a large amount of ore in the two wadis was lost through the 
tilting of the horizon, and for some distance beyond winze 18. Altogether the level had been driven 450 ft., and an 
average of 10 ft. of good ore was found.

For many years the Cuyah mine had not met the outlay 
upon it, and it had fallen about £4000 behind. This year it 
had some hundreds of pounds sterling to the good, but that was neutralized by the fact that the company was abso-
lutely essentials to continue working there. An expenditure of 
£5000 has been authorized for putting the mill, nearly 
30 years old, into good order, and to improve the reduction 
plant. There seemed a fair probability of being able to 
extract economically something like 5% of the gold con-
tained in the ore from the Vianna and Main lodes, as 
against less than 5% in the past. In the Vianna lode, as 
will be seen from the old Cu and, which was very 
encouraging. The breadth of vein is fair, and the richness 
of the ore at times simply astounding, but it is believed 
that the average of the whole might be safely taken at 
5 oitavas (1 oitava—¾ oz.). Iron lands belonging to the 
company cover an area of about 15,000 acres. The ore is 
of excellent quality, yielding 6% iron almost free from 
phosphorus. In addition to the company has about 5000 
tons of sponge iron ore which contains, as far as known, 
0.25% of phosphorus. The directors will transfer £5000 or 
£10,000 of the reserve fund to meet the extra capital 
expedition authorized for equipment to smelt the iron ore.
MINING AND METALLURGICAL PATENTS.

Specially reported for the Mining and Scientific Press.

In an apparatus of the character described, the combination of a smelting furnace, a closed chamber containing particles of carbon, a second chamber containing electric heating elements and capable of being heated to a temperature of 1000° C. by an electric current, a passage connecting the heating chamber with the lower end of the said chamber containing charcoal, a passage leading from the charcoal chamber above the bottom into the smelting furnace, a passage leading from the upper portion of the smelting furnace into the other end of the heating chamber, and a pressure device in the latter passage for forcing some of the gases from the smelting furnace into the heating chamber.

In a turbine-driven rock-drill, the herein described means for discharging the exhaust water at a higher level or otherwise against an adverse pressure; same comprising a turbine-wheel of the kind herein referred to and having its vanes arranged to permit of a large angle of outlet; a casing having a chamber for said turbine, and a discharge passage which gradually increases in area towards the outlet and which receives the water on leaving the vanes of said turbine, substantially as set forth.

HOIST.—No. 892,907. Frank P. Snow, Los Angeles, California.

A hoist mechanism comprising a frame having an abutment bearing and a gripping bearing, provided with shaft gripping projections, a shaft mounted in said bearings, a gear, and a drum loosely mounted on said shaft and means for reciprocating said drum on the shaft, extending between the gripping projections of the gripping bearing to a point outside the frame.

An ore-furnace comprising an ore-stack, a carbonaceous-fuel-burning furnace, and a flue composed of solid carbonaceous material connecting the fuel-chamber with said stack, for the purpose set forth.

In a crusher of the character described, the combination with side walls having outstanding projections and inset ribs, of an end wall located against the ends of the side walls and projecting beyond their outer faces, said end wall having a thickened portion fitted between the side walls, a stationary jaw located upon the thickened portion, side plates interposed between the ribs of the side walls and the stationary jaw, holding bolts passing through the projecting ends of the end walls and the outstanding projections of the side walls, tie rods bridging the space between the side walls, certain of said rods having their ends located in and secured to the outstanding projections, a movable jaw, and actuating means therefor including a device journal on one of the tie rods.

FILTER ELEMENT.—No. 887,349. Carl Sellenscheldt, Berlin, Germany.

A filter element comprising a frame and a grid therefor adapted to withstand the lateral pressure of the filtering material and formed of a rectilinear lattice or network of metallic wires under longitudinal tension.
The Carnahan System of Breaking Rock.

In hard rock one man can easily drill 45 ft. per shift with a No. 1 Murphy drill; 65 ft. with a No. 2, and 90 ft. with a No. 3, and he can put his holes in to take advantage of the ground the same as if he were doing the work by hand. The extreme simplicity and durability of the Murphy drill depends largely on the fact that there is but one moving part, and when one of these drills goes underground, it goes there to stay. The miner does not lose time bringing it to the top for repairs. It is well established that rock can be broken more economically by means of shallow holes, put in so as to take advantage of the ground, and shot often, than by filling a heading with deep holes. The reason why a heading is filled with deep holes, where larger mounted machines are used, is because it takes so much time to set the machine up and take it down, and it is not practical to do this more than once or twice per shift. With a machine that takes no time to set up or take down and permits the holes to be put in just as they would by hand, a great saving is effected in power and in the number of feet of holes necessary to be drilled. In order to get the best result out of hand machines, the hole should not be put in more than 48 in. They should be pointed to take advantage of the ground, and should be shot twice per shift, or oftener, or, if this is impossible, the drill must have plenty of space to work in. A small streak of ore can be kept just as clean when Murphy machines are used, as if broken by hand. All miners will admit that in ordinary ground, rock can be broken cheaper by hand than with a mounted drill if the question of time is eliminated. If this be admitted, the proposition becomes simple, for with a Murphy drill a man can drill with ease four times as much as he can by hand and use no more powder per ton of rock broken. The wear and tear of the machine is very slight. On an average they will not cost more than $3 per month to keep in repair, and they take about one-third as much air as the 2½-in. so-called one-man "baby" machines.

From the description and illustration it will be seen that the Murphy air-hammer drills are adapted to all kinds of practical mining, such as sinking, stoping, tunneling, and block-holding, and they are adapted to be used with solid or hollow steel, wet or dry. One line of repair parts will suffice for all machines, as the repair parts for a Murphy drill are made strictly interchangeable. To reach the cylinder, the oil in the reservoir must pass through a leather gasket, which is made of heavy sole leather, unperforated, through which the oil must soak. This it does just fast enough to keep the cylinder properly lubricated. This advice is more important than may appear at first sight, for miners are notoriously careless about oiling their drills. Examination of the illustration will show the simplicity of the machine, there being but one moving part. Every part can be readily removed and replaced if worn. Any one can understand it, and any one can run it. These drills are manufactured by C. T. Carnahan, at Denver, Colorado.

The Municipal Journal and Engineer has moved to 239 West 35th street, New York.

Commercial Paragraphs.

WOODS & HYDROART have removed to 356 Market street, San Francisco.

BAINBRIDGE, SHAYMOUS & CO., mining and consulting engineers, have moved to 352 Salisbury House, London.

The Central Machinery Co. announces that its head office has been moved to 15th and Blake streets, Denver, Colorado.

HENDRICK CYANIDE MACHINERY Co., Denver, Colorado, reports the sale of a complete cyanide plant to the Dixie Royal Mining Co., Dixie, Idaho.

The Driper Concentrator Co., of Fort Wayne, Indiana, has recently sold four of its No. 3 tables to the Florence-Goldfield Mining Co., Goldfield, Nevada.

The James Orr Concentrating Co., of Newark, New Jersey, has shipped 12 James simlers and 8 James concentrating tables to the Hinds Co. Mining Co., at Santa Barbara, Mexico.

The Dearborn Deco & Chemical Wks. announces that, at a recent directors meeting held at Chicago, W. A. Converse was elected secretary and chemical director and Ralph R. Browning was elected treasurer.

The Western Gas Engine Co., of Los Angeles, reports that its last year's business amounted to $250,000 and that installations were made over the entire Pacific Coast from Alaska to Mexico. It is making a specialty of a 300-hp. fluid-fuel engine.

The E. I. du Pont de Nemours Powder Co. has recently placed on the market a dynamite having a low freezing point. It is claimed by the manufacturers, that by the use of ingredients which in no way detract from the strength of the explosive, the freezing point of the nitro-glycerine is lowered to 35° F. Red Cross dynamite, as the new product is called, is made in strengths from 25 to 60% on both the straight and annoula formulas.

Publications Received.

MAP OF MINERAL DISTRICT. Madera county, California. Issued by California State Minioth Bureau, San Francisco. Sent to any address for 25 cents.

VOIDS, SETTLEMENT AND WEIGHT OF CRUSHED STONE. By Ira O. Baker. Bulletin No. 23, University of Illinois Engineering Experiment Station.

Catalogues Received.

The Jeffery Mfg. Co., Columbus, Ohio has issued catalogue No. 31-A, on crushers and pulverizers.

The Redwood Manufacturer's Co., San Francisco, has issued catalogue No. 2, descriptive of cyanide plant equipment.

The Arthur D. Little Laboratory, Boston, has issued a pamphlet which it calls 'Some things a manufacturer should know about coal.'

The Boston Co., Waterbury, Conn., has recently issued a small catalogue describing and illustrating its line of staggered-point steel belt lacing.
EDITORIAL.

THE COST of electric transmission lines for power underground does not forcibly impress the lay mind, nor, for that matter, the mind of many an engineer. An electric installation is often decided upon as the result of a 'snap-judgment' rather than after comparison of estimates. Mr. Arthur B. Foote contributes suggestive remarks on the relative costs of electric and compressed-air transmission, which we print on another page of this issue. What Mr. Foote tells us is not new, but it is so frequently overlooked that a warning to calculate instead of guess, when such problems arise, is most pertinent.

CIGARETTE SMOKING has been forbidden among all employees of the Nevada Consolidated Copper Company during hours of duty. The order is based on the simple assertion that 'the cigarette habit impairs usefulness.' Physiologists who have insisted on the emasculating influence of the pungent mixture of fumes from doctored tobacco and rye paper will be comforted to receive endorsement in the commercial estimate placed upon the effects of this form of self-indulgence by a great corporation which has developed principles of economy and efficiency to the highest point. Some one may now seek contrasts between racial energy and cigarette consumption. At first thought some startling contrasts come to mind.

TAKING STEEL production as a measure of financial conditions, the achievement of the United States Steel Corporation for the quarter ended June 30, gives great encouragement. The net earnings, aggregating $29,265,756, were in excess of those for the previous quarter by the substantial amount of $2,036,000. The earnings in May were known to be small, so that the increase is due chiefly to the output in June, a phenomenon so unusual in the steel trade that some critics have hinted at manipulation to produce a favorable appearance. A corporation which has been steadily earning profits even in times of business depression, and which was able to report an undivided surplus on December 31, 1907, of $122,645,243, could easily 'doctor' the returns for the sake of creating a good impression and stimulating confidence and activity in the world of commerce. But the genuineness of the reported earnings wins the more credence from the fact that the orders booked in July represented about 26,000 tons daily. The demand has not come from the railroads, but is chiefly a direct result of the large harvests, which have created a strong demand for tin-plate, agricultural machinery, and finished steel. There is, however, renewed activity in car-construction, and it is announced that orders will be placed immediately for six thousand steel cars for the Har- riman roads.
What Constitutes a Placer Discovery.

It had become a fixed principle in Alaska that valid location of placer claims necessitated a prior bona fide discovery of gold-bearing gravel, having a tenor such as to warrant development as a mine. Under the conditions prevailing throughout a large portion of the Territory, it followed from this requirement that actual discovery of gold in the gravel on bed-rock had to be made before valid rights could be sustained through the location of a claim. This was a less liberal interpretation of the statute than has prevailed in most of the Western States and Territories, and seems particularly onerous, in view of the short season for work and the severe climatic difficulties against which the miner has to contend in the Far North. Viewed from the standpoint of Californian practice the Alaskan restriction appears exceptionally rigid, although Judge Ross of the United States Circuit Court for the Southern District of California ruled that "indication of the existence of a thing is not the thing itself" (Nevada Sierra Oil Co. v. Home Oil Co., 98 Fed. 673, 676). Nevertheless, where the existence of a thing is so strongly indicated that its presence seems certain enough to warrant the expenditure of time and money in exploration, the courts have with great unanimity held the validity of location upon such evidence, feeble though it may be, in lieu of actual discovery of the valuable mineral in its bed or deposit. Moreover, the disposition of a locator who has performed the necessary acts to give legal occupancy, claiming to have made a discovery of valuable mineral, and having done the required work within the statutory limits of time, is so repugnant to the custom of the courts, that any reasonable proof of good faith will render his possession practically unassailable. The danger from stability of possessory right to a claim already located, even though located for speculative and not strictly legitimate purposes, is far less than the invitation to trickery and fraud which would follow by making it easy for 'jumpers' to attempt to justify re-location on the ground of technical error on the part of earlier claimants. The liberal construction of the statute makes for the higher safety and ultimate prosperity of the community.

The Alaskan case of Cook, Ridenour et al. v. David Johnson et al., locally known as the 'Junctilla case,' has been decided by Judge Gunnnison of the First Judicial District of Alaska in favor of the original locator, who confessedly had found only a few 'colors' of gold in the 'muck' or soil-covering over the gravel. Instead of proceeding to prospect the claim, he cut out the brush for surveying the lines, and constructed a cabin on the property for his own use. Subsequent claimants founded their pretensions upon a more important and conclusive demonstration of the existence of gold in workable quantity in the gravel beneath the 'muck.' The evidence of good faith, taken in connection with the provable sources of gold which, by reasoning from analogous cases in the district, should warrant a man in expecting valuable deposits, and with the work which the claimant had done, was accepted by Judge Gunnnison as sufficient to sustain the early locator's right to the property. The ruling is in accordance with the spirit generally prevailing in the Western courts.

Gold-Dredges, Large and Small.

While the tendency toward ponderous construction and huge capacity in gold-dredging appliances goes on unchecked, there seems to be a call for efficiency also at the other end of the scale. In this issue we record the achievement of a superb dredge recently built for the Folsom Development Co. in California, having buckets holding eight and a half cubic feet, and capable of digging one hundred and fifty thousand cubic yards of hard gravel per month from a depth of thirty-five feet. This is a different story from the occasional triumph of sixty thousand yards of easily dredgable gravel which produced boasting only a few years ago. Less than four years have passed since dredge-operators were seriously discussing whether the loss of time was not so much less with three-cubic-foot buckets than with those of five cubic feet that the lighter chain of buckets would in the long run outstrip the larger machine. Faulty details of construction made criticism pertinent at that time. Today it is merely a question of the amount of gravel available and the length of the owner's purse; the machine with big buckets has vindicated itself. In fact, dredges with thirteen-cubic-foot buckets are operating at Folsom, digging one hundred and eighty thousand cubic yards per month, at a total cost of three cents per yard.

The new achievements are clearly set forth by Mr. Frank W. Griffin in this issue, and his statement that progress will henceforth be along the line of perfection of detail is significant. While this is probably true for what we may term 'standard' dredges—for a truer standard type has been more nearly reached in dredges than in stamp-mills, despite their difference in antiquity—there are comparatively few fields suitable for gold-dredging on a scale commensurate with a capital-expenditure of a half to several millions of dollars. There are, however, multitudes of small placers, situated so that hydraulicling, booming, or 'blowing-down' as described elsewhere in these columns by Mr. James Park, are not economically applicable. Many toy designs have been made to fit such cases, and financial failure has almost invariably followed. Mr. H. W. Turner presented in our last issue a note on a steam-seraper adapted to a small placer in the Sierra Nevada. It is interesting chiefly as showing that a need exists for economical gravel-excavators of small cost and moderate capacity, and that meagre attention has been paid to it by engineers of training adequate for reaching successful solutions of the problem. The steam-seraper seems to offer some possibilities. It was applied once before in California in Tapia canyon of the Sierra Madre, the winch being mounted on a movable frame in which were gold-saving devices similar to those on a dredge. Light excavators have been tried in Arizona, and in Mexico, and probably in a great many
other places, and apparently they have all had a very similar record of failure. The attention of engineers might advantageously be directed to the design of small as well as large gold-dredging appliances. The field is extensive in both directions.

The concentration of gold in river-gravels always tends toward enrichment at 'bed-rock', or at intermediate clay-partings in the drift. This simple fact of observation is not as easily explainable as might appear at first sight. The analogy of concentration in a sluice is of only limited application. The concentration of coarse gold in the steeply-inclined upper reaches of a stream, where the entire mass of gravel is subject to frequent disturbance and rearrangement by floods, depends, of course, upon the same principle as that which the hydraulic miner has always employed. The concentration of gold in what are known as 'high-banks' is also comprehensible. This represents the deposition in eddies during periods of high water. The phenomenon is peculiar to all gold-bearing districts that are subject to sudden floods. The distribution of gold in 'fans', where rivers debouch from narrow valleys upon a plain, is referable to the scour of a river channel in which concentrations of gold had previously taken place, and the zones of superior enrichment through such 'fan-deposits' apparently represent successive deep-securings of the upper valley by extraordinary floods. The accumulation of gold almost invariably in larger relative amount on the bottom of the channel is not so easily accounted for. The actual turning over of the deep gravel-fill, as sand and gravel are moved forward in a sluice, demonstrably has not taken place. We have seen drill-holes penetrate the valley-fill to depths of thirty-five to forty-five feet through coarse sand, containing no pebbles larger than two inches diameter, without revealing a single gold 'color' until bed-rock was reached. Also, in a middle-Californian valley-deposit, we have seen an exactly similar phenomenon occur both on 'false-bottom' and on the true bed-rock twenty feet below it. Manifestly, the principle of sluicing has not applied in such a case. In a recent bulletin of the New Zealand Geological Survey, Mr. James Park discusses the concentration of gold in river-gravels in a very able manner, but he does not grapple with the peculiar problem we have stated here, although an extension of his explanation of the progressive settlement of gold through gravel subject to movement in a current of water is all that is needed to adequately account for the phenomenon. We must conceive a change in conditions, however, which involves a consideration of movement infinitely slow as compared with the flow of wet sand on a steeply-inclined channel. We know that the soil-covering, which may be more accurately, because more broadly, denominated the 'regolith', as suggested by Mr. George P. Merrill, is not transported to lower levels exclusively by means of wash from the run-off of the rain-fall, but when saturated with water does actually flow not unlike a viscous body. This phenomenon has also been pointed out by numerous students of soils, both in America and abroad. The same movement is indicated as a characteristic of sand and gravel-fills of river-channels, and even of broad valleys. It may be compared to the slow, steady, persistent, downward movement of a glacier. This movement has largely escaped detection, most likely because it was unsuspected. Even Mr. Park, after his critical study of gravel deposits, has failed to note it. This is probably because the opportunities to study very flat sandy valley-fills by means of a sufficient number of bore-holes to afford data for safe generalization, have not been frequent. The case is not yet absolutely demonstrated to the point of determination of velocities of movement of water-saturated sandy valley-deposits, and observations extending over considerable periods of time are needed. But the fact of such movement has been clear in our own study of placeres, and corroborative testimony will no doubt be forthcoming from others. Our attention was first directed to it from discrepancies in checking old surveys across bottom-lands consisting of typical Californian valley 'wash', which were being drill-tested for gold. The divergences showed such persistent deflection in the direction of the slope of the valley as to awaken suspicion of a uniformly operating cause not attributable to errors in surveying. A mobile mass of sand and gravel, moving steadily forward, would necessitate such variations in interstitial spaces between the grains as to facilitate the gradual subsidence of gold particles along curved lines theoretically similar to those of the trajectory of a projectile, as indicated by Mr. Park in the more mobile gravels of a shallow channel. The difference between the two cases is merely one of degree, but the 'glacial creep' of an apparently stationary deposit involves a new conception. It undoubtedly exists, and it is evidently competent to produce concentration of heavy minerals toward the bottom, given the time which Nature takes for her leisurely processes.

Silver Coin is always a troublesome article for governments to regulate. It refuses to stay fixed in value, and so it offers peculiar opportunities for juggling in exchange. Spain has for some time been afflicted with an unusual form of silver speculation. The five-peseta piece, known as a duro, very nearly equivalent to the American dollar, has been counterfeit to such an extent that over $15,000,000 worth of the spurious coin is estimated to be in circulation. This so-called 'Seville dollar' not only simulates the legend, obverse and reverse, of the legitimate duro, but tallies with it precisely in weight and fineness. The difficulty in the matter is that the counterfeiters and not the Government reaps the profit, and this is no trifling seigniorage. The Government ordered the seizure of all 'Seville dollars' presented in payment of duties and taxes, for which the gold value of the coin would be returned. As only an expert could distinguish the false from the true, the merchants declined to receive duros at all. The result was a blocking of the wheels of retail trade, and the Government was forced to hastily rescind the order.
Personal.

E. B. Kimball has gone to Alaska.

W. F. Copeland is at Caribou, British Columbia.

T. A. Rickard and Scott Turner are at Nome, Alaska.

Walter W. Wishon, of Los Angeles, was in Chicago last week.

John A. Reed, of Stockton, was in San Francisco this week.

John Noyes, of Butte, is visiting his brother at Candle, Alaska.

C. S. Hensie is in Nicaragua on examination work for London clients.

H. A. Shipman, of Denver, was in San Francisco Thursday.

James W. Abbott was in New York last week, on his way to Pioche, Nevada.

R. H. Richards, of Boston, is inspecting different mining camps in the West.

Howard W. DuBois will go to Dawson, Yukon Territory, about September 1.

Chester A. Thomas is resident manager for the Yukon Gold Co., at Dawson.

C. W. Purinton is in Vladivostok and will examine placer mines at Chokots.

J. A. Holmes, of the U. S. Geological Survey, is visiting England to study coal-mining methods.

George A. Tweedy, general manager of the Minas del Tajo, Rosario, Sinaloa, is in San Francisco.

F. G. Forshey, of the staff of the Barranca mines, Sonora, Mexico, was in San Francisco this week.

Arthur W. Jenkins has gone to Alaska on professional business. He will be gone until the middle of September.

Martin Finkbein has returned to El Paso from Chihuahua, where he has been examining mines for a New York company.

J. E. Spurr has been making an examination of the West End mine, at Tonopah, with a view to planning future development work.

E. E. Ellis, late of the Oliver Iron Mining Co., has been appointed geologist to the Tennessee Coal & Iron Co., with headquarters at Birmingham.

George H. Ashley and E. F. Lines, of the U. S. Geological Survey, are engaged in a re-survey of the Idaho coalfields, in co-operation with State Geologist Blatchley.

George Ovis Smith, director of the U. S. Geological Survey, has returned to Washington from an inspecting trip through Wyoming and Colorado, where extensive surveys of the coalfields are being carried on.

Obituary.

Donald Ray Morgan, who died at Iguala, Guerrero, July 25, after a short illness with smallpox, was a mining man, well known in Mexico. He was a native of Massachusetts and came to Mexico about ten years ago, spending some time south of Mexico City and later accepting a position with the American Smelting & Refining Co. in the Saltillo district; from there going to the San Pedro mine, at Diente, near Monterrey; after which he associated himself with the Torrén Metallurgical Co., and was instrumental in their taking over the Voladora mine, which he managed with great success. He soon after became the consulting engineer to the same company, developing many of their properties, two notable ones being the Catrillas, near Saltillo, and the San Diego, at Santa Barbara, Chihuahua; at the latter Mr. Morgan installed a large concentrating mill.

Two years ago he resigned to devote his time to private practice, and to the Mexican Mines Syndicate, in which he was largely interested. He leaves a widow, who had accompanied him on his trip into Guerrero, and who was with him at the time of his death.

Mining and Scientific Press

August 15, 1908

Engineering Societies.

The Canadian Mining Institute invites members of the profession in the United States to join in its summer excursion, the itinerary of which was given in our issue of July 15. H. Mortimer Lamb, secretary of the Institute, whose office is at 413 Dorchester street W., Montreal, will be glad to furnish details to anyone interested.

The Seventh International Congress of Applied Chemistry will be held in London, May 27 to June 2, 1909. Wm. Macnab is secretary of the organization committee, and his address is 10 Cromwell Crescent, London.
MINING Arrangements unusually transit, promising was It Lawrence planned. July is San men of 203 Morgan, 20-stamp a well depth 300 Sycamore ft. the this week George shipments, the the Eastern SHASTA 6 of be push which blocked shipments will now been cut 18 8,000,000 approximately It 8,000,000 years.

ARIZONA.

COCHISE COUNTY.

Among the interesting developments of the Warreu district during the week was the initial hoisting operations at the new electric plant of the Copper Queen Co. at the Sacramento shaft, through which all Copper Queen ores will be hoisted, and the blowing in of one of the new 500-ton furnaces at the Douglas smelter of the Calumet & Arizona Co. The converters have all been moved to the opposite side of the main smelter building to make room for the additional furnaces. With the installation of the two new stacks, work will immediately begin on the enlargement of the old furnaces, which when completed will give them a capacity of 500 tons each, and the entire smelter all the efficiency and capacity of a 3000-ton plant. The new hoisting plant and its accessories will completely revolutionize the Copper Queen’s methods of handling its large bodies of ore.—One shaft has been laid off at the Virtue adit, near Paradise, and progress is unusually slow, due to an extremely hard rock which has lately been struck. The adit is now in 320 ft., and it is expected the vein will be reached within 20 ft.—The production of copper for the month of July at the Douglas smelter was larger than for any previous month this year. The total was approximately 12,250,000 lb., of which the Copper Queen produced 8,000,000 and the Calumet & Arizona 4,250,000.

GILA COUNTY.

The forces of the Copper Creek Co., near Winkelman, are now engaged in laying foundations for the large 500-hp. plant. The boiler and all the machinery, as well as the dynamo and other electrical apparatus, are on the ground. It is expected the plant will be put into service by the middle of September. When this has been accomplished, the hoists and pumping machinery on the various mines will be operated by power contributed by this plant. There are 35 men working on the construction.—Work has ceased on the American Eagle group of mines on account of water, which cannot well be controlled until the electric plant furnishes the power for the pumping. The 60-ton concentrator is now in transit, and it is expected it will arrive in time to be erected and put in operation about the time the construction of the power plant is completed. Several buildings are being erected at Sycamore Flat for the housing of employees, a boarding-house, and company store; the latter has already been established at that point.

GAHAN COUNTY.

The New England & Clifton Copper Co. has suspended shipments from the Antietam mines. The ore is being blocked and left in the mine. Suspension of shipments, however, has not interfered with sinking of the shaft, which work is now being pushed more rapidly than before.—The New York-Arizona Gold Copper Co. continues to push forward development work on its claims. There is now considerable talk about the installation of a small stamp-mill, which in all probability will be erected within the next few months.

MARICOPA COUNTY.

Luis Killeen and associates have purchased 15,000 shares of the Buffalo-Arizona Co., paying the full par value of $1. —The manager of the Buffalo & Arizona mine, near Morristown, has gone east to purchase a 20-stamp mill, a new hoist, and other machinery. After September 1 a force of 18 men will be employed at the mine.—The new 100-ft. crosscut at the Slocum Copper Co.’s mine, near Phoenix, has been pushed through to the old Slocum shaft, where a large body of high-grade ore was found. The working force has been increased, with the intention of thoroughly developing the mine in anticipation of the construction of a mill, for which the company is now trying to raise funds.

MOHAVE COUNTY.

George and Hubert Smith are at work on the old Lookout mine, about four miles south of Kingman. In former years the mine produced a large amount of rich ore, but of late years it was allowed to lie idle. It is the intention of the owners to run a drift below the old workings and after timbering the ground, sink the shaft to a depth of 100 ft. Considerable milling ore is opened up in the bottom of the old shaft and below the caved ground.

YUMA COUNTY.

A new company, headed by George Mitchell of Los Angeles, has been formed to work a consolidated group of claims lying near Big Williams Fork. The concern is to be known as the Clara Consolidated Gold Copper Co., and is capitalized for $3,000,000. It is reported that a mill will be built on the Clara claim.

CALIFORNIA.

MARIPOSA COUNTY.

Paul Stockton, of San Jose, is opening up a large marble quarry near the Yosemite Valley railroad. The marble is of the finest quality, and grades from the dark, almost black, to a light mottled color.

NEVADA COUNTY.

(Special Correspondence).—Within a week the work of unwatering and re-timbering the shaft at the Idaho-Maryland will be under way. Three shifts will be employed. A large force will also be put at work re-opening the 700-ft. level and running a drift to strike the vein. The new vein on the 500-ft. level has been proved for 250 ft. and has widened to 10 ft. A west drift from the 500-ft. level is opening virgin country.—The Calvert & Sharp gravel mine, near Canada hill, has been hounded to Hannan, Murphy, and associates, of San Francisco. The adit will be driven ahead 200 to 300 ft. to strike the channel.—A. Becker, of San Francisco, has hounded the Bluejay and Extension properties near Maybert. Considerable development work is planned.—Work will shortly he resumed at the Gaston mine, and a portion of the mill kept running steadily. The adit is in 1400 ft., with about 2500 ft. to run. Progress is being made at the rate of 6 ft. per day.—Arrangements are being made to resume operations at the Orient mine. Eastern people are interested. The Mayflower mine, at Canada hill, has been hounded to Honolulu parties.—George Hothersall and Frank S. Morgan, of Nevada City, have hounded the Lost Emigrant mine, near Summit.—At the Buckeye, a drift is being run to develop a promising ore-shoot and to eventually connect with the Cold Springs channel.

Grass Valley, August 10.

PLACER COUNTY.

Work at the Azalea has been temporarily stopped.—The agent of a San Francisco company is negotiating for the group of quartz mines owned by the Robert Waugh Co., and the gravel mine of Morgan & Green near Bold Mtn. —W. S. Fletcher has made the second payment on the Home Ticket mine. He has also begun the extension of the Blackhawk adit, near Forest Hill.—Lawrence & Gaylord have driven their adit a total distance of 300 ft., and expect to go at least 100 ft. farther. The material is a tate and is so soft that augers are used in removing it.

Work on the Hidden Treasure continues with 10 men. The sawmill is now running to fill the big orders of W. S. Fletcher for flumes along the line of the old Breece & Wheeler ditch.

SIERRA COUNTY.

The Balaklala Co. has taken an option on the Rogers store and store-building at Coram, with a view to going into the mercantile business when the smelter starts. The Company plans to also open a store at the Balaklala mine.

It is reported that the Hazel Mining Co. will increase the capacity of its 20-stamp mill at French Gulch, making it a 30-stamp plant. The Company employs 110 men at its mine and mill.

SIERRA COUNTY.

Chick & Aldrich have hounded the Buttes Saddle mine and are receiving bids for driving a 1000-ft. adit. It is reported that they will also fix up the mill and operate it.—I. H. Holley, who last year purchased the Chipsa mine, has interested a number of Eastern people and is now preparing
MINING AND SCIENTIFIC PRESS
August 15, 1908

for a thorough overhauling and renovating of the mine and mill. Mr. Holley expects to have the stamps dropping by October.—It is rumored that the Keystone will be started up again after a close-down for repairs.—The Plumbago mine has recently put in new compressors and dynamos.—Asa Wilson has purchased the interest of his partner, Jason Frye, in the gravel property near Mt. Vernon.

SISKIYOU COUNTY.

(Special Correspondence).—Negotiations between the United States & British Columbia Mining Co., of Boston, and Wintering & Osgood, for the purchase by the former of the Big Cliff group of claims on Russian creek, Salmon River district, were broken off last week on orders from Boston, greatly to the surprise of their representative, who had expected the property and made a very satisfactory offer. Mr. Osgood arrived from Seattle Saturday and a new deal is pending. The company's operations on Woodrat bar, the Wm. Quigley ranch, and several other river ranches known to be underlaid with placer gold.—J. A. Brent, who, with a party of California capitalists, recently filed on the bed of the Klamath river for a distance of many miles, will soon have a suction dredge at work below Hamburg bar. The timberers are being hauled to the site now.—G. H. Coffin, of Terminal Island, Cal., closed a deal last Saturday for the purchase of the Missis slipay placer mine, on the Klamath river at the mouth of Grider creek. W. T. Grider has worked this property since the 'sixties,' slushing only when he wanted money. Some seasons his clean-ups netted enough to carry him along for several years, and the mine would lie idle until his funds ran low. The new owners will work the property on a larger scale. The price paid was $15,000.

Yreka, August 10.

TULEAR MINES.

The men who have a bond on the Sonnet have started work.—The Jumper mine, at Stent, is again working. The force will soon be increased.—It is reported that S. L. Bright has sold his Dutch property and that the new owners will start work at once.—The shaft of Arbona is being unwatered and the mill repaired. The development will be centred on the 200 and 200-ft. levels.

COLORADO.

CLEAR CREEK COUNTY.

(Special Correspondence).—Work was resumed this week upon the driving forward of the Prudential adit, Republican Mtn., the portal of which is in the corporate limits of town. The bore is now in 750 ft., and the Magenta vein should be reached in a few feet. It is the intention of the company to equip the property with a heavy compressor-plant, the power to be secured from the Two American Sisters M. & P. & E. Co. plant. W. C. Hood, of Georgetown, is general contract with the company, and work has already been started. This property is situated on Republican Mtn., the bore being in over 600 ft. The first vein to be reached is the Pay Rock Extension.—A payment of $50,000 on the $200,000 purchase price of the American Sisters mine was made August 1. Jas. A. Means, representing a syndicate of New York capitalists, is satisfied with the past development of two months, and as a result will start more extensive development.—Adams & McClosky, leasing on the Allium through the Ocean Wave level, have shot into an 8-in. streak of ruby silver and gray copper, assays of which are as high as 450 oz. silver. A winze is being put down, and as soon as the ground under the 200 of the old adit has a depth of 50 ft. driving and stopeing will be started.—The Raymond adit is being driven steadily forward, being now in 500 ft. Another vein has recently been reached, which is heavily mineralized, and as soon as the hanging wall has been reached driving will be started both east and west.—The Domino adit, on Paynes peak, is now in 450 ft. A lode was recently intersected, but after driving 40 ft. the hanging wall has not been reached. A number of streaks of galena ore have been struck that are from 2 to 3 in. wide. H. Cochran is making a few tests on the property from the De Beque and Arapahoe districts, and the results are to the effect that there is a genuine boom in evidence. A total of more than 200 men are at work, with more going in every day. The Coffin mine seems to be making the best showing, and shipments are being made direct to the smelters at Denver. In the lower adit the orebody is from 5 to 6 ft. wide, the average content being about $35 per ton. The revenue, 1907 and since.—T. Cunningham, manager of the Revenue Extension M. & M. Co., has put a force of men to work this week upon the Star property, in the Peru district. Operations are being carried on through the Malley level of the Revenue workings. The Revenue was worked up to the east end-ines, a streak of ore being left that is from 8 to 16 in. wide, Driving is to be started to open the ground.—The United Hydro E. Co. has entered into a contract with the Central Colorado & Denver Co., for the installation of a complete power-service, by which all possible power requirements of Clear Creek and Gilpin counties will be supplied. The plant of this Company is at Georgetown, but by the terms of the contract a sub-station is to be erected at Idaho Springs, at which point excess power will be delivered by the Central Colorado Co. The transmission line is now being run between Denver, and will be furnished from November 1, 1908. Fred P. Dewey, of Georgetown, is manager.—Two carloads of smelting ore are being shipped each week from the Black Eagle mine, on Chicago creek. The ore is a medium grade, returning from $23 to $25 per ton in gold. Operations are being centred on the fourth and sixth levels.—J. G. Roberts, of Idaho Springs, is building a complete ore-sorting and concentrating plant at the Jackson mill, which is to be put up at the Lamarrate dump. Through this device the entire dump matter is to be treated. Mr. Roberts recently took a long-time lease on this property, and purposes reducing the material only to such a grade as to make a good milling matter, which will be delivered at the Jackson mill for final reduction. It is estimated that there is nearly 200,000 tons of this material available at the mouth of the Adit, and proofs delivered show the property is worth many times the $10,000 purchase price. The adit is being driven ahead, and a number of stringers of heavy lead ore are exposed in the breat. The bore is in 450 ft., and from surveys the junction of the Friar Tuck will be reached in a few feet.

Georgetown, August 10.

OLPIN COUNTY.

During the past week Emery, Holmes & Co. shipped a carload of smelting ore from their lease of the San Juan mine, on Quartz hill, to the Argo plant, in Denver, which is expected to run between one and two ounces gold per ton.—A car of concentrate was shipped from the Penobscot mill, in Gabble gulch, to the Argo smelters, by the second road last week, and will be delivered this week from the Champion mill, on Beaver creek.—The recently incorporated Union City M. & M. Co. has purchased the Wiedmann property, near the Apex divide, and has already started the construction of a shaft-house and foundations for holing engine.

LAKE COUNTY.

In accordance with the plans of the management and lessees, the No. 4 shaft of the Iux property, on Breece hill, was closed down with the completion of the work of the last shift on Friday of last week. Men are now at work getting ready for the necessary repairs, the arrangements including much re-timbering and an entirely new foundation for the engine. Three weeks will be required for the completion of the work.—A. W. Moon, of Denver, has secured control of the Foremost adit, on Chief Mtn., near Frisco, and will start operations in a short time. The old adit has been driven into the hill a distance of more than 800 ft. Mr. Moon contemplates prospecting the ground
through which the bore has passed. There are several places from which he thinks shipments can be started. Work has been started on the Moyer dump, in California gulch. This material is sent to the plant of the American Zinc Extraction Co. It contains a sufficient quantity of lead to make the operations on the old dump successful. A small force of men is employed.—Lou R. Johnston and his associates who have taken a lease on the Tribley property, on Breece hill, have started prospecting through the Yak tunnel. Their work is being done at a depth of 1300 feet.

OURAY COUNTY.

George Crawford was in Ouray last week, accompanied by L. Gentry, of Chicago, who, Mr. Crawford claims, will advance the money to pay off all indebtedness and start work at once.—The Mickey Breeze will open within the next two or three weeks, according to recent dispatches. The upper workings of the abandoned property will be developed, and it is expected that the Breeze will be a dividend-payer after the work is well under way.

TULLEY COUNTY.

A test run was started last week at the mill on the Stratton's independent, for the purpose of determining the best method of treating some of the ores produced from the mine. At the conclusion of these tests, and possibly one on the sulphide ores, it is reported that the big mill will start actual operations.—The total length of the Roosevelt deep-drainage tunnel is now 2372 ft. During the month of July a distance of 263 ft. was made, which shows a falling off from previous months. This is accounted for to a great extent by the extreme hardness of the rock in the heading, which has been almost impossible to break. However, new machines are being used, and with new steel better progress is being made, and it is probable that during the present month the required distance will be made.

IDAHO.

BONNER COUNTY.

(Special Correspondence.)—The crew at the Panhandle smelter will be increased this week from 50 to 100 men, and with all possible speed the improvements in the plant will be pushed. A visit of inspection was made last week by several officials of the Montana Mineowners' Association, which will furnish most of the ore. The plant will be ready to blow in within another month.—J. C. Hague, of Spokane, is incorporating a new company to operate his group of claims on Tryptac lake. The claims have been under development for several years and are thought to have good orebodies in galena.—The MacNicholas-Watts Mining Co., which has been purchasing mining property in this region for some time, has recently taken over 12 claims on Garfield bay of Lake Pend d'Oreille. They are said to have invested $250,000 within recent months.

Ponderay, August 8.

SHOSHONE COUNTY.

(Special Correspondence.)—The Hogan mine plant is to be doubled, making it a 40-stamp mill, and cyanide tanks added. The mill is running steadily, and it is stated that $250 per day is being cleaned up, although the mill is operating on low-grade ore.—The Black Diamond claim has been purchased by Spokane men and is now under development.—The Emogene, a quartz property, is being developed by a small crew, and a saw mill is being erected near the property.—The Buster shaft is being sunk as rapidly as possible. F. W. Bradley is expected to visit the mine in a short time, and it is said he may decide to have a power plant built for extensive development.

mine for carrying on development work. The mine is an old location and has much development. Two shipments of ore for test purposes have been made by the Bulletin mining company, and both have resulted in the mining of the ore with good results. The shaft is being sunk to reach the 300-ft. level, where a copper shoot is expected. The Canyon Creek Fraction has uncovered two streams of galena, several inches wide on the foot and hanging walls. The width of the veins has not been discovered. A contract for 100 ft. of tunnel work on the Silver Mountain has been let to W. W. Bradley. The assessment of 3 mills per share has been levied on the stock of the Pine Creek Mining Co., for development purposes. The amalgamated Stock Holding Co. has been organized at Wallace, to operate a group of six claims on Pine creek. Good galena showings are said to have been made. The Capitol Mining Co., on Two Mile creek, is driving a 2200-ft. adit to tap its vein at a depth of 2690 ft., which is 500 ft. below the present workings. Some high-grade galena has been struck. The Idora Mining Co. has paid off the last of its $12,000 mortgage and will resume operations shortly. Work will be continued on the adit, which has crossed one lead and is being pushed on, and also in driving on the vein. Hand-drilling will be used this fall, and in the spring, machinery will be installed. A contract for 240 ft. of tunnel work on the Amoondix property has been let. The property has good galena showings, and has shipped a small amount of ore.

MISSOURI.

Jasper County.

(Special Correspondence).—A considerable advance in the price of zinc ore marks the week. Zinc has been quoted from 15.50 to 15.60 per ton for 60% zinc. An unusual demand for ore was noted among the buyers from Wednesday to the end of the week. The total value of the lead and zinc output for the week was $196,714. The American Beauty No. 2, south of Webb City, and the Yellow Dog, the largest plant north of the city, have closed down indefinitely on account of the low price. A number of plants have started up again, after a brief shut-down, and many others are contemplating an early re-opening and are engaged in present in unwatering the mines. The Midway mound, northeast of Joplin, where a number of rich properties were located, is to be opened at once. The Evans Mining Co. has taken over the old Pearl C. plant and, with adjoining companies, is draining the ground. The Red Fox, an adjoining property, will also be re-opened. The latter has a day's strike, and both properties are worked at the 350-ft. level. The Midnight mine, west of Joplin, one of the richest of the younger properties, is to be re-opened after several months' shut-down. The drill showed that the entire lease is underlaid with rich ore, and an old water-course penetrated by the shaft showed very rich galena and zinc-blende in the walls of the natural cave. The Columbia mine, in the same locality, is to be re-opened by Bendelaris & Cook. The old shaft, down to 140 ft., will be sunk 11 ft. deeper to catch a lower, and richer run of ore recently found. A concentrating plant is on the ground. The Engineers' Zinc Co., at Webb City, one of the largest plants belonging to Frank Nicholson, will start work at once in the north Webb City field. Plans were made to re-open early, but a delay was necessary on account of installation of some new machinery. The past fortnight has noted a number of rich strikes throughout the district. At the Stewart mine, in Belleview, a shaft has been completed into the lower run of ore at 150 ft. The ore is zinc-blende, and though only a small amount of development work has been done, the ore taken out seems to indicate a large deposit. The Florence Mining Co., operating a large flotation mill, has had a number of rich strikes of the past few months. A shaft penetrated a rich body of zinc-blende at 75 ft., developing a 27-ft. face of ore. A second shaft showed a 25-ft. face, and a third shaft entered the orebody at 14 ft., striking silicate, zinc, and galena. A mill is on the lease. The Martha E. mine, near the old Newaycove-in-a, is proving a valuable property. Seven drill-holes on the 10-acre lease show ore. The shaft is breaking into ore at 15 ft. A drift will be run at 250 ft. Two shafts have been installed to handle the water, which is a more serious question since the shutdown of the American Beauty. The deeper deposits are zinc-blende, while the shallower runs are galena. T. N. Davey is having his land near Porto Rico drilled. The drift penetrated ore from 130 to 150 ft., and later from 150 to 200 ft. encountered a good run of sheet-ore. The ground will be divided into shafts and run and subdivided for mining purposes. The Ground Floor Mining Co. moved the mill to the west part of its lease and is now sinking two shafts and taking out rich ore. During the low ore prices the Company developed the ground, employing only a few men, but the force has recently been increased. Large pumps have been installed at the Needmore, in Oronogo, where a rich strike has been recently made on a 10-acre lease. It will take some time to drain the ground. The ore was struck at 170 ft., continuing to 250 ft. The upper levels will be sub-leased by the present Company, which is reserving the deeper runs for its own use. One drill-hole entered the ore at 10 ft. and continued in ore to 250 ft. A mill will be built. The Alba camp is becoming quite active again after the financial depression. A number of companies are prospecting and developing the leases, both in the old camp and farther northwest, along Spring river. The Quick Seven Mining Co. is perhaps the most active at present. A steam-hoist and derrick are being installed, as well as a lift-pump. The ore is being cleaned upon hand-jigs. The Company has bought all the timber on the lease. The Holton Mining Co. has opened up a rich vein of zinc-blende in a drift shaft from the shaft. The ore was struck within six feet of the shaft, and the drift heading is now out 20 ft., with rich ore showing on every side. The Riverside Co., adjoining the Quick Seven, has begun sinking its shaft deeper to catch the run lying below the present drifts. A number of new mills are being built or planned in the district. The Coosahna L. & Z. Co., at Porto Rico, has let the contract for the new work on the plant will be begun at once. The mill will be on the Horton land, near the Church-Mitchell lease. Seven drill-holes on the 20-acre lease showed ore at 200 ft. A double-compartment shaft is being sunk, in which the skip system will be used. The Waddell Mining Co., north-west of Carthage, has erected a 100-ton mill on a 40-acre claim. The Clifton property lies at the mine and the work on the plant will be begun at once, as the trial run of the mill has been successfully made. The Endeavor Mining Co., on the old Prudential lease, has completed its 25-ton plant and now has one of the best equipped mills of that capacity in the district. The new shaft is being rapidly sunk while the old shaft has been fitted up. Air-planes ready for operation. A few more days will be required for the adjustment of the machinery, and the mill will then be run steadily. A 250-ton mill has been completed at the Lucky Jim, west of the city, but will not be run until ore prices advance.

Joplin, August 8.

Lawrence County.

(Special Correspondence).—It is reported that every drill in the Aurora camp is active. A number of rich strikes have been made, especially on the land of the Federal L. & Z. Co. Shallow strikes show galena and the deeper ones show rich zinc-blende. Scott & Coleman have developed a tract east of the city showing a run of zinc-blende at 250 ft. A shaft was started and reached the 150-ft. level before it was abandoned on account of water. Recently the work was again taken up and heavier machinery installed. The machinery will form a part of the concentrating equipment. This land adds 240 acres to the productive area of Auroras. The Black land is the scene of a prospecting and development campaign. This land has been one of the best producers of Aurora, having shipped over 15,000,000 lb. of lead ore in seven years. The present development bids fair to place the land in its rank among the leading producers. One of the richest strikes in Au-
MINING when having machine The The ft., six modern 13c. Denver A block trail is the Free equipped bucket an The Stewart Jesse being Pardy the Beneficiadora one the about 'Cia. reported $500 by made owned Brierly, ide".

Lincoln County.

B. S. Nunn has sold a one-half interest in the El Modica claim, at Pioche, to Robert McLaughlin for $1000. A number of men have been put to work extending the adit, which starts from Main street. The remaining one-half interest belongs to Robert Schofield, of Pioche.—The installation of the gasoline engine has been completed on the Pioche-Pacific property, and two shifts have been started to work. The plant is modified in every particular, and will permit of the shaft being sunk to a depth of several hundred feet. The camp of Kendall is attracting considerable interest, due to the fact that shipments are to be started to the Needles smelter. This new camp is 22 miles due south of Searchlight. The famous Plute Springs are 4½ miles to the west. Camp Leadville is five miles farther south, and Chiquita and Juniper are, respectively, 5 and 10 miles to the east.

Nye County.

A new compressor has been ordered by MacNamara, and no time will be lost in installing it as soon as the machinery arrives, when several more machine-drills will be put in operation. The regular work will be continued in the western part of the mine, from which all ore has been extracted since the suit was begun.—The sinking of the Tonopah shaft and drift is being pushed from the bottom of the Red Plume shaft of the Tonopah Mining Co. continue, and good progress is being made in both workings. Having plenty of ore blocked out to keep their 100-stamp mill running for a long time, the management is devoting much of its time to the gaining of depth, and thus proving up its ground far below the present workings.—The Manhattan Co. has resumed operations, and at present the work of raising on the 200-ft. level is in progress. As fast as the ore is taken out it is being hauled to the Peterson mill for treatment. The company has a 1500-ton contract with the reduction company.—The Manhattan Gold Bar Co. has put two men at work sinking a shaft on its estate and development will be rushed.—The Springdale mill, at Beatty, is rapidly nearing completion, and will begin operations next month. The plant of the property of the Springdale Mining & Milling Co., and may handle some custom ore in addition to company ore.

White Pine County.

The mill of the Stuart Gold Mines Holding Co., at Cherry Creek, was formally started recently. The mill is equipped with four Nissen stamps, Pierce amalgamator, Callo\' screening and tank, and Willey and Frue vanners. The plant will handle custom ore, as well as the Company's own ore. Three shifts are now working at the plant of the Spring- toe Valley Smelting Co., at Smelter, and three converters are in commission. The mines are shipping about 1500 tons per day, 1000 of which comes from Copper Flat and 500 from the Cumberland Ely.—The Giroux is putting another pump into the Alpha shaft, in anticipation of a much larger flow of water at any time.

MEXICO.

William C. Seddon, of William C. Seddon & Co., and other capitalists of Baltimore, Md., have obtained control of a vast tract of mining property, 1,500,000 acres, in Mexico, through which runs the Campan, Yaqui River & Pacific Railroad. They also have control of the Douglas Copper Co., at Fundidion, Sonora, Mexico, who have completed a copper and gold smelting plant. It costs $15.75 per ton to produce electrolytic copper, according to Theodore Douglas, president of the Company. On a basis of 5.64% copper recovered, with copper at 15c. per lb., and $6.35 per ton gold and silver, the ore has a gross value of $23.67, from which, after deducting the cost of production, $15.73, leaves a net profit of $7.94 per ton. The San Rafael Mining Co., of Pachuca, has let the contract for a new plant for the treatment of the slime to White & Newcomb, metallurgical engineers, of Mexico City. This will be the largest slime plant in Mexico.—Cía. Explotadora y Beneficiadora de Metales de Zacatecas, Zacatecas, will erect a concentration and cyanidation plant, A. C. Luck, engineer for the Company, is making tests in Denver of a shipment of the ore.
Special Correspondence.

LONDON.

Some six months ago I referred to J. H. Collins’ work in re-opening the Wheal Kitty, one of the old tin mines in the St. Agnes district of Cornwall, and mentioned that while certain companies in Cornwall were spending large sums on modern plant, expecting no profit, Mr. Collins was more than meeting his expenditure by means of what superior people are apt to call out of date methods and machinery. The succeeding six months’ work, that is to say, the first half of the current year, has fully confirmed Mr. Collins’ expectations, and the mining operations have yielded a substantial profit, in spite of the fall in the price of tin. The six months’ output of ore has risen from 3,337 tons to 3,093 tons, and the amount of concentrate sold rose from 51½ tons to 101 tons. The average yield increased from 37 lb. to 43 lb., per ton while the price fell from £56 to £58. The total income rose from £5,241 to £8,949. The mining expenses during the last half year were £59,95, royalties £44, directors’ fees and management £41, leaving a balance of £23,78. A thousand feet of development have been pushed through in the new workings, and the remaining 4,800 ft. is very promising. In order to put the mine permanently on a paying basis it is highly desirable to sink the main shaft an additional 500 ft., and properly equip it. It would also be of advantage to extend the dressing-plant. These two objects can be gained by the expenditure of £16,000. I ought to mention that the issued capital is only £20,000, of which only £19,000 has been called up, and there is a large share in the property now being purchased for the purpose of working capital. Of the profit made during the last half year, only £252 is being distributed as dividend, being at the rate of 7¼% per annum, and the remainder is being placed to the fund for carrying out the proposed new work. It is to be hoped that shareholders and others will come forward with the new capital. It will all be spent economically, and on lines adapted to Cornish mining, and none of it will go in experimental work on electric pumps.

The readers of the Mining and Scientific Press are kept well posted by your local correspondents as to the doings of the Tyee Copper Co. at Vancouver Island. This property is owned in England; the largest shareholders, in fact the controlling factors, belong to the Siemens group. Though the mine was closed in October last, the smelter has been put into first-class working order; and by this means the capacity is now being doubled. The strong point in the Company’s favor is that steamers call at Ladysmith, where the smelter is situated, for coal, and there are great inducements for shippers to send ore there by these steamers. The policy of the Company is to get into contact with and to offer special facilities to ore producers in British Columbia and Alaska, and from all we hear there seems to be strong probability of large supplies coming forward from these districts at no distant date. The chances of doing business with Mexico and the United States are not so great, owing to the existence of smelters nearer at hand. The Company is fairly well supplied with working capital, and has a reserve fund of £50,000, besides which the individual members of the Company would readily come forward with funds to secure smelter contracts whenever the opportunity may occur. At the present time the smelter is not working up to its capacity. During the year ended April 30 the furnace was in blast 187 days, and treated 42,307 tons of ore, of which 6,004 tons came from the Tyee mine and 36,767 were custom ore. No roasting is done, as most of the ore received contains no excess of sulphur, and the lead opened up in the furnace. The product of the furnace during the year was 397½ tons of matte, averaging 39.9% copper, 18% zinc, silver, and 18 dwt. gold. This was all shipped elsewhere for refining. In all probability, later on, the Company will do its own refining.

One of the most unfortunate mining speculations ever entered into by English investors is the Dundee Iron Ore Co., Ltd., which was formed seven years ago to acquire large tracts of low-grade iron ore deposits in Norway. The method of dealing with these ores comprised Edison disintegrators and Edison magnetic concentrators, after which the cleaned ores have to be briquetted. The Company was promoted by Sir Joseph Lawrence (who, by the way, introduced the Linotype machine in this country) and it was supported by a number of leading iron-masters in the north of England and South Wales, who recognized the advisability of the process. The Edison磁分离机 was a machine invented by Professor Edison, which was operated by electric power. The Company enjoyed for a time great popularity, owing, to a large extent, to the magic of Edison’s name. In this country Edison is supposed to be the most wonderful and successful inventor, that ever existed. There were not a few people who prophesied disaster when the Company launched out on such a magnificent scale to operate untired processes. At first £2,000,000 capital was issued. Afterward £500,000 debentures were put forth. Then another £500,000 of second debentures were offered for subscription, but hardly any were taken up. Finally, this year, a loan of £30,000 was raised on the security of prior-lien bonds, which have to be issued somehow or other this year. The directors are now trying to issue £100,000 worth of pre-preference shares, and there appears to be very little chance, especially in the present open market, that any of these new shares will be made. Altogether the Company is in a parlous state, or, in the words of the satirist, ‘in the devil of a mess.’ The technical difficulties encountered by the Company have been varied and continuous, and at every meeting of shareholders some different excuse had to be given for the want of progress. First it was the unexpected cost of harnessing the Edison apparatus, then the smelting of briquetting had to be abandoned and new experiments made; afterward the crushing plant had to be reorganized; and later on the concentrators had to be modified. At the present time the chief difficulty is that labor is unobtainable, owing to the unpleasant conditions set up by the little dust. An effort is being made to modify the transporting apparatus which is the chief offender in kicking up a dust, and Mr. Robinson of belted fame, has been commissioned to suggest changes. The Company is also confronted with the cost of production in relation to the state of the iron-ore market. The cost at present is estimated at 5s. per ton, and it happens that the market-price for similar raw ore is only 4s. 6d. The costs do not include interest, maintenance, and depreciation, but all the same, the directors cling to the hope that the output of 300,000 tons per year is attained, the costs will be lowered, and a sufficient profit earned. The policy of the directors is now to close down the works entirely until the new conveyors are erected, and until the market for iron-ore improves. I don’t know whether the necessary money, some £75,000, for the new conveyors will be raised or not. Altogether the outlook for the Company is about as black as it can be.

TORONTO, CANADA.

Report of Canadian Department of Mines.—Iron Possibilities in British Columbia.—Electric Steel Production at Niagara.—Silver Discoveries in Montreal River District.

The Mines branch of the Canadian Department of Mines has issued a report covering the fiscal year 1907-8, and giving, in addition to statistical information previously published, the results of investigations carried on by its officials as to the mineral resources of Canada.

Einar Lindeman, who made an examination into natural and other conditions in British Columbia, bearing upon the feasibility of establishing a large iron industry, a project which has been entertained for some time by extensive capitalists, reports concerning the iron-ore deposits of Vancouver and Texada islands. He states that the magnetic ores mix in a large collection and that the iron products will be of very high quality. The ore is found in the vicinity of the Klawach river, and Quinsam river in Vancouver Island, are sufficiently ex-
tensive to supply a blast-furnace for many years. These ores are high in iron and low in phosphorus, and though as a rule they have high sulphur content, that element is not present to a sufficient extent to unfit the ore for smelting. A ample fuel is assured, as the coal output of Vancouver Island for 1907 was estimated at 1,325,000 tons, and coke to the extent of 17,000 tons was produced. This coke contains 15 to 16% ash, but this could be reduced to 12% by more careful separation of the shale. Limestone is abundant and of relatively high quality, and the raw materials and bituminous coal are situated for transportation, should a furnace be established anywhere on the Coast. The high price of labor is a noticeable drawback, and another consideration to be borne in mind is the necessarily limited nature of the British Columbian market for some years to come, which may make it necessary to find an outside market for the surplus output.

The report devotes some attention to the electric smelting question, with a view to the solution of the problem of producing steel directly from the ore. It is thought that the technical difficulties hitherto encountered may be met by the application of the Lash steel process to the electric furnace. Success has attended experiments with this process made by the Canadian Lash Steel Process Co., of Niagara Falls, in an open-hearth furnace, indicating its probable efficiency, and the raw materials are abundant, else the process, finely divided ore is mixed with carbon, a certain quantity of finely divided iron, containing much carbon, such as cast-iron borings or granulated pig-iron, sawdust, and fluxes. By the open-hearth 'ore-process,' a mixture of approximately 75% pig-iron and 25% iron-ore can be worked up, but in the Lash process a much larger percentage of carbon can be used, and with a small proportion of iron rich in carbon. A typical mixture for the 'ore-process' is divided per centage composition. Iron-ore, 54; cast-iron borings, or granulated pig-iron, 27; sawdust, 4; limestone, 4; coal tar, 3; coke, 2; total, 100. When these are finely divided, intimately mixed, and heated to a high temperature, the reactions that occur are similar to those in the open-hearth furnace using the 'ore-process.' In using the Lash mixture in the open-hearth furnace, it is necessary to have a bath of molten metal, otherwise it could not be heated to the temperature required to produce reaction without losing carbon. But with the electric furnace no difficulty of that kind is experienced, since the gas in an electric furnace is neutral, in contradistinction to the oxidizing atmosphere of an open-hearth furnace. The great economy of the process lies in the substitution of a large amount of both iron and coke from its present position. The Lash mixture in the electric furnace have been made on a small scale with successful results, the yield of metal amounting to 98% of the metallic content of the mixture. While the average cost in Canada of the raw material for producing 100 tons of steel ingots in an open-hearth furnace is $25.75 per ton, the cost of using the Lash mixture is an electric furnace is given as $16.22 per ton. Different electric furnaces are being tested to ascertain the type best adapted for the application of the process.

A very large amount of prospecting has been done in the Montreal River area, but comparatively little development work has been accomplished this season, owing mainly to want of capital, together with transportation difficulties. One of the most advanced properties is the Shirley Cragg location in the river district, where 25 men are engaged in development work. Test pits have proved the occurrence of native silver, and the vein has a width of 3 in., while much of the wall-rock will make milling ore. The Moose Horn mines, in the Montreal River area have passed into the hands of a New York syndicate, which will thoroughly develop the property. The Lower Lorraine camp is rapidly progressing. New buildings are being erected, and a deplorable condition of the Greene interests, which has resulted in the closing of the Sierra Madre Land & Lumber Co.'s saw-mill at Madera, which is practically a subsidiary of the Greene Gold-Silver Co. This leaves the people in the lumber camp destitute. Likewise the closing of the Concheño mine, and consequent dismissal of a large number of men adds to the hardships in the district. Concejo had developed into an excellent property under the

MEXICO.

The articles in the proposed new mining law that limit the rights of foreigners and foreign companies, continue to receive attention, but the excitable stage seems to have passed. In the meantime railroad and transportation subjects are largely to the fore. The most important of these, of course, is the merging of the Mexican Central and Mexican National into the National Railways of Mexico. Early in June it was reported that over two-thirds of the merged lines had been turned in, and that in the course of the following month, after the return from New York of Pablo Macedo, the Government's representative on the National railroad, the new company would be organized and take over the actual management of the consolidated roads. This has not been carried out in full, however. The new company has been organized, and E. N. Brown, president of the old National Lines, has been made president of the merged lines, the National Railways of Mexico, but the management has not yet been taken over, and will be put in charge of the majority of the new securitores. Of the Southern Pacific's Guaymas-Guadalajara line, the extension from Guaymas was completed and the first train run into Culiacan, Sinaloa, on July 23, amid great enthusiasm, though a heavy storm prevented the demonstration that had been planned. At the Guadalajara end the track is being laid on the first 12 kilometres from Orendain, and over 6,000 men have been ordered to double its force, now consisting of 1000 men, so as to keep the grading advancing rapidly, and complete the road to Tequila, about 25 miles from Orendain by November. On the Guanajuato Mineral Belt railroad, the force has also been increased in the effort to finish the road this year, and many of the tunnels have been eliminated, and a surface route taken instead, with the same result in view, that is, completion this year. On behalf of the Rio Grande, Sierra Madre & Pacific, now running between Juarez (El Paso), and Nuevas Casas Grandes, in Chihuahua, it is stated that H. R. Nickerson, president and general manager, formerly vice president of the Mexican Central, and one of the best posted railroad men in Mexico, has raised $5,000,000 with which to continue the road from Orendain to the international line. On behalf of the Rio Grande, Sierra Madre & Pacific, now running between Juarez (El Paso), and Nuevas Casas Grandes, in Chihuahua, it is stated that H. R. Nickerson, president and general manager, formerly vice president of the Mexican Central, and one of the best posted railroad men in Mexico, has raised $5,000,000 with which to continue the road from Orendain to the international line. On behalf of the Rio Grande, Sierra Madre & Pacific, now running between Juarez (El Paso), and Nuevas Casas Grandes, in Chihuahua, it is stated that H. R. Nickerson, president and general manager, formerly vice president of the Mexican Central, and one of the best posted railroad men in Mexico, has raised $5,000,000 with which to continue the road from Orendain to the international line.
former owners, Corrigan and McKinney, of Cleveland, Ohio, to whom it may now revert back, as something like $1,000,000 is still due from the Greene company. Beyond Creameo in the Pinos Altos Mining Co., which latter is preparing for the erection of an immense concentrating and cyanide mill, orders having been given last fall, but later held up because of the general monetary crisis. The concession held by Greene for the prospecting rights over some 3,000,000 acres in the western part of Chihuahua expires early in December, and it is not believed that in his present financial condition he can make a renewal or extension, so the immediate future prospects for new work in this part of the country are really brighter than they have been for some time back.

**Butte, Montana.**

Amalgamated Copper Co.'s Production.—Davis-Daly Estates Reorganization.—Butte & Superior.—Treatment of Zinc-Copper Ores.

Butte & Balaklava.—British Butte Dredge.

The Amalgamated Copper Co. produced in July 20,000,000 lb. of copper from the Washoe smelter, representing the output of all the Amalgamated companies, the North Butte, and the Butte Coalition. It was the record-production of the Washoe smelter, and at the lowest cost per pound in the history of the plant. The cost of production by the Washoe is gradually being lowered by the general development of the mine and by treating a larger amount of ore. Formerly, when the record output was between 15,000,000 and 17,000,000 lb. per month the Washoe employed 3000 men with a monthly payroll of $300,000. Now, with a production of 20,000,000 lb. it employs 2000 men at a cost of $215,000 per month. Formerly the plant handled an average of 9000 tons of ore per day; now it takes 11,750 tons, but still more than the normal capacity, and the plant is being crowded to its utmost limits on account of the shut-down of the Boston & Montana smelter at Great Falls. The latter plant will be repaired by September 1, and all the Boston & Montana ore will be shipped to Great Falls again. The Boston & Montana output has, since the first of June, been limited to about 40% of the normal, because of the Great Falls smelter being out of commission. The Company is shipping about 1800 tons of ore daily to the Washoe. The North Butte Co. is mining about 1400 tons of ore per day, shipping to the Washoe. Half of the quantity is first-class and half second-class ore. The July production was 4,125,000 lb. of copper. The Butte Coalition is confining its mining to the Jarus and Minnie Heinz mines, and is shipping 550 tons of ore to the Washoe daily. The Anaconda Co. is operating all its mines at normal capacity, with the exception of the St. Lawrence, the output from which is restricted on account of gas coming from the fire in the old stopes, which interferes somewhat with mining on the upper levels. The Parrot Co. is sinking the Little Mina shaft deeper, and is cross-cutting on the 2100-foot level of the Parrot mine. The Company is mining about 490 tons of ore per day, but the average yield is not much in excess of 2% copper.

Richard R. Vail, for eight years in the engineering department of the Amalgamated Copper Co., has been appointed superintendent of the East Butte Copper Mining Co. Mr. Vail has also been with the Pittsburg & Montana Copper Co., the mines lying just east of those of the East Butte. He is a graduate of the United States Military Academy and has served as Chief of Engineers, and the latter and other head officials of the Amalgamated have a high opinion of Mr. Vail's ability. His appointment may be regarded as significant of the friendship of the Amalgamated and other big companies for the East Butte.

The Davis-Daly Estates Copper Co. is carrying on development work in the Colorado mine in a small way, and all other properties of the Company are closed, awaiting the efforts of F. Augustus Heinz, chairman of the executive committee, to re-finance the enterprise. According to the plans discussed the stockholders will have to provide the funds for a rehabilitation. The idea seems to be to organize a new company, and levy an assessment of $2 per share.

On some recent buying from Duluth, the stock of the Butte & Superior Co. advanced from 87c. to $1.10, but there is nothing in the development at the property to justify such an advance; nor is there any better prospect for opening a copper mine than there was months ago. The Butte & Superior has opened a big vein of zinc ore, but it has little commercial value because it can not be shipped and treated at a profit. In that respect the Butte & Superior is no different from other Butte companies having similar zincky ore.

La Francisco Copper Co. is still experimenting with the Steele dry-process zinc separation, but it is not certain that it will succeed. In a small way at an experimental station in Texas the system works perfectly, but like many other processes it failed when put into actual and constant use. The trouble seems to lie in the complexity of the Butte zinc ores, and in the high percentage of minerals that are lost in the dust from the plant. The ores carry zinc, lead, iron, copper, gold, and silver, and the percentage of neither zinc nor lead is high enough to make it profitable to mine the ore for either, with the other associated by-products. However, the combined value is high, probably three times that of ordinary copper ores. There is so much of this kind of ore in Butte that a solution of the problem would make Butte the greatest zinc as well as copper camp in the world. The cost of transportation makes it prohibitive to concentrate the ores, and the smelters demand that the concentrate run a certain percentage of zinc, and to bring the product up to that point increases the loss by dust. The ore carries considerable gold, but the zinc smelters will pay only $9 per oz. for the gold in the concentrate, the pleb being that the gold is of no value as it interferes with another high-grade zinc ore, and requires additional handling, the zinc smelter not being equipped for extracting gold. Until a zinc smelter is built at Butte the zinc ores cannot be mined at a profit. Several years ago the Montana Copper & Zinc Co. tried another dry concentration method at the Alice mine and proved it a success on a small output, but as soon as an attempt was made to operate it on a large and paying scale it failed because of the increased care and attention required. Before its plant was destroyed by fire the Montana Copper & Zinc Co. changed its system by the introduction of a partial wet method of concentration.

The Butte & Balaklava Copper Mining Co.'s stockholders, at a meeting recently, voted to pool the stock. The purpose of the arrangement is not quite apparent, the unique explanation being that the company is trying to carry out the purpose of pooling the stock with a bond of trustees and the control of the property in the hands of the present management, and prevent any rival company from getting hold of the stock, taking possession of the property, and shutting down operations. The six acres of ground of the Butte & Balaklava had been peddled on the market a long time before North Dakota and Minnesota farmers were induced to take it. The latter capitalized the six acres for $2,500,000, and eventually unloaded on R. B. Dear and his associates. Development work has been carried on for a year, but with no important results. It is claimed that 127,637 shares out of 210,000 outstanding have been pledged to the pooling agreement, or 22,536 more than a majority. The trustees authorized the issuance of trustee certificates representing the six acres, which certificates are negotiable on the market in the same manner as the actual stock, the only restriction being that the trustee certificates will carry no voting power, the latter remaining with the trustees for the purpose of retaining control of the management of the Company.

Several large reserve dams have been built on the Butte & Superior property, and plans are being made to install the big dredge, which is being built in San Francisco. The dams hold a combined capacity of about 10,000,000 gal. of water in reserve for dredging purposes. The dredge will be one of the largest in the world. It is expected that the plant will be in operation by the first of next October.
TONOPAH, NEVADA.

Settlement of ‘Apex-Suit’ between McNamara and West End. — Ore Discoveries. —Mitpah Shaft. —Belmont and Montana Reports. — Financial Conditions.

The most important event which has taken place in Tonopah in many months has been the settling of the ‘apex-suit’ between the West End and the McNamara companies, which took place on July 24. The settlement was a ‘just-handle’ one in which the McNamara got everything asked for. This is the end of a suit which was started in December 1906, when the West End enjoined the McNamara from taking out ore from a vein vertically under the McNamara claims, but which the West End continued ‘appending’ apex to its case never once coming before the court, but was to have been heard on August 2. There has been a small army of lawyers, experts, surveyors, and workers on this case for several months past. The leading lawyers were Curtis H. Lindley for the McNamara, while the lawyers for the West End were Peck and Solinsky and W. E. F. Deal. The experts were C. H. Moore, J. W. Chandler, and A. C. Lawson, of the University of California, for the McNamara, and W. B. Ker and Wm. H. Shockey for the West End. It is thought that Josiah E. Spurr, who has been in camp for the last two weeks, was working for the West End. The agreement is that the workings of each mine shall be confined to the ground within vertical side-lines, and that extra-lateral rights shall be abandoned. This decision means much to Tonopah, and will allow free development in these two mines, which are known to exist, and where there is probability of finding much more. Vigorous work to determine the apex of the ore has already led to valuable discoveries. Especially interesting is the finding of ore on the western boundary of the McNamara on the 300-ft. level within 10 ft. of the Ohio Tonopah claims, which now belong to the West End. This gives great hope of the discovery of orebodies far west of anything now known in Tonopah. It was certain that a wise move on the part of the managers of these two companies to settle the suit amicably, and it is to be hoped that their example may be imitated in other apex-suits.

This discovery of ore by the McNamara has called attention to the territory west of the producing mines of Tonopah, and may have influenced the sharp legal battle now in progress for the possession of the Red Rock and McNamara mines. These properties are being held by armed men for the Tonopah Extension. The Tonopah Banking Corporation also lays claim to them under a lien. It is likely that this matter will soon be settled and work resumed. The question of ownership is complicated by the fact that the boundary line between Nye and Esmeralda counties passes through the two mines. Tonopah is watching with the hope of a dispute, and other neighboring miners, as the former president of the Tonopah Mining Co. for the failure to prospect this mine in depth when it was in bonanza several years ago, when the expense would not have been felt.

The managers of the Belmont company think they have found good ore below the intrusion, but local engineers disagree on this point. Nearly all of the mines have found quartz-dikes below the intrusion, but though these bodies are strong, often 50 ft. wide and continuous for several hundred feet on the strike, they have thus far proved nearly barren. Assays from the quarz-dikes have usually shown 2 to 3 oz. silver per ton, and in only a few cases have assays as high as 10 oz. been obtained. The Montana company is running a long north cross-cut to prospect under the twelve claims it owns north of its present workings. All of these workings, in what may be termed virgin ground, are important, and discoveries in any of them will give a great stimulus to mining in Tonopah. I have lately been interested in comparing the annual reports of the Belmont and of the Montana companies. Both own mines in Tonopah, but the Belmont mill is at Millers, twelve miles away by railroad, while the Moutana mill is in Tonopah. The first thing noticeable is the cost of power at the Belmont mill, $36.25 per month per hp., or $401.20 yearly. This cost was to be reduced by the adoption of electric power from the Nevada California Power Co. The total cost per ton for milling is given by the Belmont report as $7.325 per ton, on a total of 34,1441 oz. To this must be added about 75c. for transportation, making a total cost of $8.525 per ton. Against this cost the Montana reports for milling show 15,748, oz., or an average of $5.625 per ton. This shows a difference of $4.605 in favor of the Montana mill. The Montana ore, if there is any difference, is possibly more difficult to treat than that of the Belmont. The Belmont mill is now running some of its stamps on ore from the West End, Midway, and other Tonopah mines. Their minimum charge is about $12 per ton for treatment. It is evident that if the Montana mill begins to treat ore it can soon put the Belmont out of commission.

Business is quiet in Tonopah, but there is a much better feeling than prevailed a few months ago, and a sharp revival of business is looked for this fall. Many men are returning from Rawhide, and some of the other over-bommed camps. There has been little re-building in the part of town which was burned a few months ago. Work on the large hotel, which was started right after the fire, of the panie in October 1907, has been resumed and it will soon be opened. The hanking situation has been strengthened out. The Nye and Ormsby Bank, thanks to the efforts of its president, Frank Golden, has weathered the storm, and will pay off all deposits in full, beginning January 1, 1909. The State Bank has given up and is now in the hands of a receiver, whose report shows great mismanagement. The Tonopah branch is especially condemned for its open-handed loaning of the bank’s funds. The other two banks are in good condition.

JOHANNESSBURG, TRANSVAAL,

An era of record-breaking continues to prevail upon the Rand, and we are experiencing an endless succession of new standards of attainment in gold yields, working costs, dividend declarations, in recovery percentages, stamp duty, and other respects. The Rand is now in a state of efficiency that is maintained below the surface. Last year, it may be recalled, a record was made in the sinking of the Brakpan 7-compartment vertical shaft 201 ft., from 1599 to 1894 ft., one month. This same mine now has created a new record by the sinking of its inclined from the bottom of the vertical shaft to 223 ft. in the month, with still-terrifying. The size of the incline is 19 by 7 ft., and the angle of inclination for 9 degrees. Following upon the decision of the Chemical, Metallurgical & Mining Society to appoint corresponding members of council in various mining countries abroad, another effort to extend the scope and utility of the organization is being made by the establishment of a branch in Rhodesia, where it is hoped that periodic meetings will be held for the discussion of local technical affairs, with special advantage to the gold industry of that country.
Society’s thousand members, nearly 10% are domiciled in Charterland. In a land rising so speedily in importance in the mineral world, and confronted with such a diversity of complex problems, the benefits of a more ready interchange of knowledge and experience would be incalculable. Expansion has been largely stimulated by the influx of small capitalists of Rand experience, who have often been found to repeat mistake after mistake merely for the lack of knowing the special difficulties of their predecessors and the means by which troubles are overcome. The amount of practical information available for intending operators in regard to mineral occurrences or working conditions, is at present deplorably meagre. Apart from gold, the production of metals—as in the Transvaal—is of small account. A report now issued by the Secretary for Mines for 1907 shows the principal yields to have been in value: gold, $19,675,000; silver, $8,900,000; copper, $23,500; chrome iron, $8,800; and gems, $138,000.

After years of fruitless negotiation, a scheme has now been evolved which will shortly lead, almost without doubt, to the amalgamation of the Village Deep and the Turf mines. The combined operation of the two, the former being a producing mine with a heavy debt, and the latter being a development station, has long been acknowledged as the shared interest of the shareholders in both concerns, but the relative valuation of assets has been a difficult matter. The Village Deep is now crushing about 28,000 tons per month with 180 stamps, for a return of less than $7 per ton. If the amalgamation scheme is carried out, the crushing capacity will be speedily raised, and the full benefits of the other producer’s practices will be gained. Financial considerations appear, however, to be the chief factors in favor of the consolidation.

The mill and cyanide works to serve the far greater amalgamation in the East Rand, the Simmer Deep, are progressing steadily and appear upon inspection to be sure of completion before the stipulated date of September 1. The first sod was cut about eighteen months ago, but as the principal producer’s property is dependent upon the uncompleted power-station of the Victoria Falls Power Co., and upon the readiness of the mines for stopping, no pressing haste has been necessitated. The mill, of 300 stamps, as now erected, is not only to serve the Simmer Deep, a property aggregating about 1500 reef-bearing acres in extent, but also the Jiquar. We thus see this single instance in which a single area commenced six independent deep-level mines. The great magnitude of the area served by this one plant, more than twenty times the holding of the Crown Reef or Ferreira, gives the concern special significance, but the results of operations will be watched by none with greater interest than the metallurgist. For the characteristic of magnitude marks even the units of the plant itself. Constructed principally of steel, the battery, which has already had a trial run, comprises 300 stamps of no less than 1670 lb. each, which will be further weighted up if required. In spite of this great weight, anvil blocks are not adopted. The boxes rest upon concrete foundations of over 100 tons, with merely a ½-in. rubber cushion between, and are held by easily accessible bolts. Each unit of 10 stamps is driven by a 20-h.p. engine, without sharing dimensions. In the mill, the pulp is to be classified by means of cones, the peripheral overflow of which is more efficient than that of the more common pyramidal boxes, separating out the product for the tube-mills, of which four, 5½ by 23 ft., are in course of erection. The cone overflow runs into collector-vats of 60 ft. diam., of which there are ten installed; treatment-vats are of somewhat larger dimensions.

The slime-plant consists of 13 enormous conical vats, the largest in South Africa, of 70 ft. diam., and 12 ft. high at the sides, increasing to 17½ ft. in the middle. The whole plant, at present considered to stand on a 72,000-ton per month basis, is laid out with special regard to the requirements of probable expansion and with magnitude in all corner pieces. It is highly the leading principles of advanced Rand mechanical metallurgy proved successful by W. A. Caldecott upon the plants of the Consolidated Gold Fields under his control. Even allowing for the absence of a power-generating plant, which the scheme of purchasing electricity allows, the methods of mill construction have led to a very substantial saving in capital expenditure per stamp, in comparison with other installations. Heavy stamps and high duties, with auxiliary tube-mills, are now the order of the day upon all Consolidated Gold Fields properties. At the Tulipard’s Vlei Estate over nine tons per stamp per day is recorded with stamps of 1550 lb., considerably less than the maximum specified for the Simmer Deep. The importance of the tube-mills is well shown by the Simmer & Jack mine, where the shaking-tables below these re-grinders win from 10 to 15% of the gold recovered from all sources.

The declaration of the June output at 574,973 fine ounces for the Transvaal, being 8900 oz. below the Matter total, is satisfactory in view of the shorter working time. Considered from the standpoint of the actual rate of production, the industry records a yield of 19,116 oz. per day for June as compared to 18,774 oz. for May. The profit aggregate for 49 leading companies is maintained at approximately $4,350,000. After being several months the lesser producer, though always the premier profit-maker, the Rand deep-mining position of prominence over the Simmer & Jack, with 26,450 oz. as against 25,995 oz. The Robinson Deep comes third, with 20,888 oz. Labor returns show no appreciable change, the month’s native recruiting brings in 93,600 ‘boys’, with a net gain of 375.

The position of Sidney Jennings, formerly consulting engineer to Eckstein & Co., has been filled by H. Stuart Martin. This appointment has caused surprise in some quarters in view of Mr. Martin’s complete lack of local experience in Rand mining problems, his high reputation having been built up in the world of British coal mining. The reduction of working costs underground appears to be the foremost task to which the new chief advisor will be called upon to apply himself.

SALT LAKE, UTAH.

New Two-thousand Ton Mill of Ohio Copper Co. — Large Tonnage of Ore Developed.

Much satisfaction is felt over the resumption of work at the Ohio copper mine, in Bingham, following the announcement that the bonds authorized by the Board of Directors for a new mill, a year ago, have been fully underwritten. The general manager, who had been in the East for five months, returned on August 6, with instructions to proceed with the project without delay. The mill, the initial capacity of which is to be 2000 tons of ore per day, could be made ready within 90 days, as the building is completed and practically all the equipment, excepting a battery of Wilfey tables, is on the ground, and the latter has been ordered. It will take a little more time to get the mine ready, as the Mascot adit is to be continued another 300 ft., when connection will be made with the upper workings of the mine by means of a raise to the main double-compartment shaft. The Mascot adit is to be used for transportation purposes, and it is figured that the costs of moving ore to the place of milling near its portal will not exceed 15c. per ton. The proposed new mill occupies 337 by 391 ft., and is of steel construction; the slime plant, 115 by 242 ft., is also of steel, and similar to the main building. Both were erected by the Minneapolis Steel & Machinery Co., and cost approximately $240,000. The mill will be equipped with two 24 by 16-in. jaw-crushers, four 20 by 6-in. jaw-crushers, eight 26 by 10-in. rolls, 146 jigs, sixteen 7-ft. Chilian mills, and 382 Wilfey tables. The slime-plant will be equipped with 72 Wilfey slime-tables, 150 Callow tanks, and 12 bullides. The mill is divided into four separate sections, each driven by independent motors. All machinery is of the latest design, to insure low costs of operation and maintenance. The Company owns 1480 acres of ground in the vicinity of the mill, which is to be used for a tailing dump. When completed the mill will represent an investment of little more than $1,250,000.
Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Boiler scale 1/8 in. thick probably causes a loss of 18% of the fuel burned under the boiler, and the same scale if 1/2 in. thick will cause a loss of 60 per cent.

Gold telluride does not volatilize below 1100°C. In a current of air, however, less than 0.1% of gold in an alloy with tellurium will be volatilized. Gold in alloys with lead, copper, and other metals is volatilized along with them, and corrections have to be made for such losses in bullion assays.

An air-lift pump is an uneconomical device unless the different parts are correctly proportioned. All dealers in compressed-air machinery supply such apparatus, but a home-made lift would not give satisfactory service. More economical use of air could be made by delivery to an ordinary steam-pump. Greater efficiency can be attained if the air be preheated by passing through a coil in a small sheet-iron box stove.

Gold solvents are few in number, as compared with the solvents of all the common metals, except platinum. The two cheapest solvents are potassium or sodium cyanide, and chlorine. The latter used in solution for leaching gold is growing in favor. It has been applied in that way at Mount Morgan, Australia, with brilliant success, for some years. Such open-vat lixiviation with chlorine-water is also being used at Goldfield, Nevada. There are no other solvents available at moderate prices to which gold is as sensitive as to these.

Zinc is less efficient as a precipitant than a zinc-couple with some other metal such as lead. In practice such a couple is made by immersing the freshly cut zinc-thread in a solution of 10% of acetate of lead. Agitation in the solution results in a chemical interchange, zinc acetate passing into solution, and lead being precipitated as a film on the zinc-thread. A great objection to this method is the large percentage of lead remaining in the gold precipitates, this being often as high as 20%. Where the precipitates are cleaned up by fusion with litharge and cupelling, such an objection does not apply.

The steam siphon is the simplest of all pumps, since it has no movable parts. It consists of a vertical discharge-pipe, open at both ends, through the side of which enters a smaller pipe having its end bent np. The lower end of the discharge-pipe dips into water, and the small pipe is connected to the steam boiler. The steam, issuing from the small pipe, carries with it the air in the upper end of the discharge-pipe, tending to create a vacuum in the lower end of the pipe; the water then rises in the discharge pipe and is carried out with the steam. The steam siphon is limited to lifting water a few feet only.

Gold precipitate, often called zinc-slime, is more commonly cleaned and reduced to gold bullion by roasting and melting than by treatment with sulphuric acid. For a time the sulphuric acid method was the more popular, but there is a noticeable return to the older treatment. By careful roasting there is little loss by dusting, and none that can be proved by volatilization. The slime, from which part of the zinc has been eliminated by roasting, is melted with fluxes, enough sodium nitrate (ordinary commercial ‘nitre’) being added to oxidize the remaining zinc and other metallic impurities.

Deputy mineral surveyors are disqualified from making surveys of mining claims in which they have any interest. Aside from this there is no restriction which could possibly preclude their right to make a survey, valid for patent, of claims belonging to a company for which they were working on a salary. The distinction between the character of their relationship involved through the employment being temporary or permanent has no importance. It is conceivable that a corporation might have interests sufficient to maintain a deputy-mineral surveyor on such work for an indefinite period, and might engage his entire time and pay him a monthly salary; any discrimination between such an engagement and another in which the surveyor’s time was not unrelentingly employed in surveying for patent would have no force. But any interest, direct or contingent in the property, would alter the case at once.

The hectograph is a convenient cheap device for reproducing reading matter or diagrams. It may be made and used as follows: soak 6 oz. of ‘carpenter’s white’ glue in 8 oz. of water for about 12 hours; then slowly heat the mixture, to which 20 oz. of glycerine has been added, until all the glue is dissolved and the whole is of an even consistence. Do not let the mixture boil. Pour into a shallow rectangular tin pan, say 10 by 14 in. by 1½ in. deep, and when cool the hectograph is complete. Prepare the copy for the sheet to be reproduced on a good paper using special hectograph-ink, which may be purchased from dealers in stationery. A substitute may be made by dissolving in water the lead of an indelible pencil. Special hectograph ribbons may be procured and type-written copy prepared. Place the copy on the hectograph, face down, being sure that it is in intimate contact in all places. Allow it to remain several minutes, in order that the ink may penetrate into the pad. Remove the copy and replace it with a clean sheet of paper, which when removed will show an exact duplicate of the original. Among the advantages of this scheme is the fact that different colors may be reproduced together, and that diagrams and reading matter may be made on the same sheet. From 50 to 100 copies may be made from one original. The hectograph should be washed thoroughly after using, preferably with lukewarm water, and when dry is ready for use again. The pad should be re-melted occasionally.
Discussion.

Readers of the Mining and Scientific Press are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

Standardization of Mine Accounts.

The Editor:

Sir—At a time when the standardization of mining terms and accounts is occupying so much attention, the expression of individual opinions should be encouraged. The subject is of such general interest that a public discussion providing the means of exposition and enlightenment of ideas, would, I take it, be welcomed by those to whom the final arbitration of this question should be left. The difficulties in the way of securing the general acceptance of any plan of standardization are no less manifest than the advantages obtainable, and both points have from time to time been ably dealt with by engineers and others. It is with a view, however, to promote a discussion on the broad aspects of the case that the following notes are submitted. Considering the advantages first; one of the greatest benefits to be secured would seem to be the harmonizing of ideas, tending to unity of purpose between a mine manager and the board of directors.

The language of mining and the language of finance have grown independently of one another, and small wonder, for there has been no dictionary of the one and much license in the other. The suggestion of a manager harassed by technicalities which he cannot share because he cannot adequately translate them, will not be unfamiliar. Such an one may well experience a harrowing sense of unimportance when next he sees his yearly report, which, complete with analyzed accounts of departmental costs, has laid upon him the altar of finance; he may even feel envious of the dominance in the balance-sheet of such high titles as capital, depreciation, property, premium on shares accounts, and their kin, which he himself has never fathered. I have even known a manager who had to ask his book-keeper for information regarding his own work because he had not a month to spare in which to disentangle the requisite data. Such things do not tend to harmony, and it is possible that a like want of appreciation of the relative merits of financial and operating accounts is also to be found among shareholders. The fault is with ourselves. If the several operating mine-accounts had just as definite a meaning as 'property accounts' and rather more than 'depreciation,' financiers would clamor for their universal adoption. Shareholders might even be trusted with them.

Perhaps one of the greatest obstacles in the way of standardization of mine accounts is to be found in the natural disinclination of the authors of many excellent systems to admit the want of anything better. Such systems have perhaps been fashioned to meet certain requirements and undoubtedly 'fill the bill,' or they may be the result of long and varied experience, and be capable of more or less universal usage. The arrangement, however, may be based on certain views of the distribution of minor accounts, and these views may be correct. It is not beyond the bounds of possibility, though, that such correctness does not imply universality of opinion, and so A's system, which is excellent, and B's system, which is better in B's opinion, may by their very perfections apparently militate against any course which might make operating-accounts other than the nondescript things the average shareholder thinks them. The question arises, cannot the main objects of standardization be attained without treading on the toes of A and B? It may be granted that all mining undertakings have certain objects in common, attained by many different ways and means. It is suggested that the common aims may be so described as to be capable of being represented each by its separate account, which accounts may form the basis of standardization, while ways and means may be provided for by subsidiary accounts, which may be divided and subdivided to meet individual needs and views as required, but are all finally apportionable between the accounts for the common object achieved. For example, it will be conceded that three purposes which are common to all mining undertakings are: (1) finding ore; (2) extracting it; and (3) treating it.

Take the first two headings and consider them in connection with three sets of conditions:

(a) Where diamond drilling, as in South Africa, goes far toward establishing the existence of ore-bodies, to open up and work which, extensive hoisting plant is so far necessary as to form a predominating feature of cost.

(b) Where, as in Nevada or in Mexico, for instance, sinking through an overlying formation is a first step in the process of finding ore.

(c) Where, as in the higher altitudes of the Sierra Nevada, water is scarce, the workings are approached by adits, but hoisting in a shaft is still resorted to, and pumping is partly or wholly for the benefit of treatment.

Hoisting and pumping will evidently acquire very different values in connection with the finding or extracting of ore under these different conditions, or conceivably at different times under the same conditions. Were a a universal condition of mining, there might be an excuse for calling hoisting a main-account, but evidently the importance of hoisting as a factor in mining is variable, and again in the case of b it is the extra difficulty attending development that has to be emphasized by the cost of hoisting in the first instance, whereas if such cost be relegated at first to a hoisting-account, and left there, this lesson is lost. In case c, pumping may possibly be no necessary adjunct to either finding or extracting ore, whereas at one period or another, in case a, pumping might be wholly necessary to the first process. It may be said that, from an engineering point of view, at this rate it would be of little use to standardize accounts, if it is to be held that, for example, extracting ore itself is at one time to include pumping, hoisting, and traming some miles perhaps, and at another time that it means just breaking rock and putting it in a chute. The answer to this is, I think, that two objects are to be gained by standardization,
from an engineering point of view. First, the possibility of comparing methods in different localities. Second, the possibility of comparing costs under similar conditions. The first object infers a variety of methods, to compare which a basis is necessary. Such a basis of comparison would most suitably be the purposes aimed at which are common to all cases. The second object implies a knowledge of conditions, and this knowledge throws the necessary light upon the meaning of the accounts employed.

A definition of a primary operation then would be: a distinct step in the course of finding, extracting, or treating ore, which is not for the benefit of a subsequent step or steps, except in so far as finding leads to extracting, and the latter to treatment. If this definition be adhered to it seems that the number of possible primary accounts are actually limited to: (1) development, (2) stoping, (3) ore transportation, (4) any one or more treatment processes, such as amalgamation, concentration, cyaniding, smelting, refining, etc.; to which may be added: (5) administration, (6) mine equipment, (7) maintenance. This list of accounts must include all expenditure.

Next to be considered are the secondary accounts for ways and means, examples of which are: stoping, development, hoisting, pumping, crushing, re-grinding, power, shop, assay-office, office-expense, foremen, traveling-expense. In further explanation of the views taken, a comparison of two methods of treatment may be considered. Let us assume that there are two plants, one of which treats its ore by stamp-milling, amalgamation, concentrating, and cyaniding, the other by concentration alone; certainly the total cost of treatment is not to be compared in each case, except in the way of comparing methods; neither is the cost of concentration to be compared, if in the one case Frue vanners alone are used, and in the other case there is a complicated treatment by crushers, rolls, trommels, jigs, screens, classifiers, Wilfley tables, etc., except on the understanding that in one case it represents the whole cost of treatment, whereas in the other it forms but one step toward this end. With a knowledge of the conditions, however, these concentrating costs are always available for comparison. In the same way, three distinct treatment-processes are benefited by crushing in the first instance cited, whereas in the second case the ore is crushed for the purpose of concentration alone. The fact is, as before stated, that one does not wish to make general comparisons of costs without a knowledge of conditions, and if each primary account for treatment is understood to begin and end with certain stages, the object of standardization can be better served by a broad classification than otherwise, while individual requirements may be taken care of in as much detail as conditions warrant by the series of secondary apportionable accounts.

This last stipulation brings us to a consideration of the meaning of the term to be allotted to, and the delimitation of the functions of, the several accounts, whether primary or secondary. The following definitions are submitted: Mine development; primarily this term should be held to imply all steps in connection with the creation of reserves. Unfortunately, however, there are instances known to all of us where work, with this worthy object in view, has failed in its achievement; consequently the definition must be broadened to the extent of including prospecting. Instances are not unknown where what might be termed haphazard cross-cutting is profitable, some of the work being productive of results, and some not. In such a case the whole cost would be charged to development. In other instances the possession of large concessions warrants a policy of prospecting pure and simple, independently of the working of the main property. In this case a subdivision of the mine-development account into prospecting and development proper might be necessary. The fact remains, however, that all such work, whether prospecting or not, is carried out with the object of finding ore. It is therefore meant to be development, and as such should be charged. Development, as all other main-accounts, includes expenditure directly chargeable, and apportionments of some secondary accounts, as hoisting, pumping, power, and foremen. The costs directly chargeable will include everything necessary to the carrying on of the work at the time, that is to say, all labor and supplies necessary for the breaking of ground, and equipment necessary for continuing to break ground with the object of finding ore. The costs chargeable to development continue until the next step is initiated. This step is stoping development. There will probably be differences of opinion as to whether this account should be called a main-account or not. The opinion held is that it is exclusively for the benefit of stoping, and that no useful purpose would be served by introducing such a term into the list of main-accounts. It is no less capable of definite explanation, however, and should include all work done in preparation for stoping established ore-bodies, including preliminary provisions for ventilation in working the stope, and for handling the broken ore. This account is also chargeable with an apportionment of power, hoisting, and foremen. Stoping will include the expense attached to breaking rock in established stopes, including sorting and handling of waste found in the stope, whether such sorting be done underground or on the surface, delivering ore to the surface through shaft or tunnel, delivering waste similarly or using it as filling, breaking waste rock for the purpose of filling work-out stopes, and all other expenses attendant upon the continuation of stoping work, such as timbering, apportionments of hoisting, pumping, power, and foremen.

Ore transportation is to be treated from the mine depository to that point where the first step in ore-treatment, or for the benefit of treatment, is taken, with apportionments of power and foremen. Crushing includes breaking and crushing in crushers, stamp-batteries, rolls or mills, until the first step in reduction or treatment commences, with apportionments of power and foremen. Treatment processes, besides including apportionments of crushing, power, shop, and foremen, will include all expense attendant
upon driven-machinery, and regular ‘wear and tear.’ Mine equipment will include nothing but repairs to previously finished work, as re-timbering, re-laying of track, secondary equipment of shafts, repairs to chutes, etc., and may include apportionments of hoisting, pumping, and foremen. Maintenance will include expenses for repairs to existing surface works, buildings, and plant, in exactly the same way that mine equipment refers to underground works. Administration will include all fees and salaries in respect of head-office expenditure, salaries of manager, superintendents, assistants, assayers, and surveyors, the whole office, assaying, surveying, legal, and traveling-expense. Power generation and transmission to departmental line-shafts or users being in one account, for example, cost of fuel, engineers, firemen, construction and up-keep of flumes, ditches, dams, electric-transmission lines, etc., including labor and supplies. Shop includes carpenters’, blacksmiths’, and mechanics’ shop-expenses. Nearly all work done can be charged direct to primary accounts, but the running of shop machinery and up-keep of tools, and the salaries of the outside foremen and his officials, should be included in this account, apportioned monthly according to work done. All assay-office expenses are chargeable to administration. This account will not include retorting and smelting, which is often performed by the assayer, but will refer only to labor and supplies in connection with assaying proper. The contention is that assaying is done merely as a guide to technical direction. Office-expense is primarily to include all clerical work. The foreman account will include the supervision of mining operations, including the salaries of foremen and all officials directly under their orders, such as time-keepers, mine-store keeper, and shift bosses. Mine hoisting and pumping will naturally be charged with their apportionment of power used.

The adoption of such self-explanatory denominations and generalization would, it is contended, go far toward removing the objections that now exist in the minds of many accountants to the charging of all expenditure direct to working-costs. Let it be once understood that the business of a mining company has to do with expenditure and profits arising from operations in half a dozen or more well-defined channels or departments, and each of these departments will acquire a concrete value in the minds of financiers. Such channels are shown in the primary accounts. The inclusion of a general expense account is an admission of inefficiency. Let such an account be left to those who are interested in obscuring main issues. I take the stand, then, that all current operating expenses can be included in one or other of a hard and fast series of accounts. It now behoves us to step gently as we approach the domain of special expenditures. Keeping in view the ever-recurring question, what is the ultimate object for which expense is incurred, let us consider what is the essential difference between expenditures, thus far considered, and special expenditures. It is suggested that this difference may be summed up as follows: current expenses are for the benefit of the immediate period of time, and are such as are necessary for the carrying on of work during that period. Special expenditure is for the benefit of a greater period of time, whether of the immediate as well as future periods, or of a future period alone. This difference need be no bar to the treatment of special expenses in the same way as current expenses. There is one other subdivision of special expenses, however, namely, expenditure provided for out of revenue, and expenditure provided for out of specially raised funds. Again, we see no reason why the ultimate object of special expenditures need be obscured. It may be taken as an axiom that no work will be put in hand unless for a concomitant advantage, or until it is needed. Capital has to be sunk for the undertaking, and whether this capital be set aside out of revenue or borrowed from an outside source, the work undertaken must be charged with the cost of the loss of its earning power. The advantage referred to must be more or less clearly defined in the minds of those responsible for the undertaking, and the period of time requisite for the amortization of the outlay by profits accruing is a matter of calculation. Hence we arrive at the conclusion that all special accounts are to stand charged with interest on the money provided for them. The rest is simple: a suspense account is used, the special expenditure is charged to it with interest, and monthly apportionments are written off to the primary account or accounts benefiting throughout the period of time decided upon. All special expenditures may be gathered together and referred to a general suspense account, which may be called a ‘floating general account,’ and which will show at a glance the total amount sunk in special accounts, and the amount still outstanding and chargeable to the primary operating accounts.

‘Property account’ now remains out of all the capital accounts. Let it include the purchase of mineral claims alone and give it a three-year life. The principle of development-redemption is of course sound, but need not interfere with a general scheme as outlined in the above suggestions. The limitations of this paper are eunely felt. The omission of all reference to conditions applying to placer-mining, dredging, etc., and the handling of stores and mine-supplies, is intentional, but indulgence is craved for many other instances in which the details of working in connection with the carrying into effect of suggestions briefly made, would appear to be ignored. The remark regarding property-account is a glaring instance. The scope of the ambition which I entertain is that in the standardization of mining accounts, which will surely be carried into effect, the principle of ultimate reduction to a few main accounts for common objects achieved, will find a place, to the end that such accounts may be universally adopted in balance-sheets.

Ymir, B. C., June 29.

Conical-Bottom Tanks.

The Editor:

Sir—In your issue of July 25, Walter Neal asks the question: "Why not build flat-bottom tanks and
allow the slime to form its own cone, instead of building conical-bottom tanks for slime treatment?"

For the reason brought out later in the article by Mr. Neal, namely, that the slime forms too steep a cone, it is not practical. It is, however, practical to use the settled slime for the support of a false conical bottom inside the flat-bottomed tank, and the difficulties of construction are thereby obviated. At the plant with which I was for several years connected, the following method of construction is used for both settling-cones and conical-bottom agitation-tanks.

First a perfectly tight, flat-bottom tank is built, and inside this a false conical bottom is placed. This false bottom is roughly built, and no effort is made to make it tight. On filling the tank the pulp flows under as well as above the wooden cone, so it requires very little support. After draining the tank a few times the slime settles and packs between the false and real tank-bottoms, making a perfect and permanent support for the wooden cone.

San Francisco, August 1.

Electric Versus Compressed-Air Transmission.

The Editor:

Sir—Refferring to an article entitled 'Underground Air-Compressors', in your issue of August 1, I wish to point out what I consider to be some misleading statements. To quote from the article: "The underground compressor, taking electric power at practically the same potential as a compressor at the surface, had the advantage of saving, first of all, the capital-cost of the pipe-lines, and was thus able to generate compressed-air at a lower pressure... " (because of the loss of pressure due to transmission in the pipe-lines). This statement would lead one to suppose that an electric transmission-line costs practically nothing compared to the cost of one for transmitting the same power in the form of compressed air. This is not by any means the first time I have seen this asserted, and never have I seen it contradicted.

As a matter of fact, judging from my own experience, the electric transmission-line will cost more, in most mines, than that for transmitting air. This may not be the case on the surface, where electricity can be transmitted at a high potential over small bare wires carried on poles, while the air-pipe lines have to be buried, but underground-conditions in most mines are quite different. If an electric transmission-line is expected to be permanent in a wet mine, especially when there is acid in the water, all conductors must be in the form of lead-covered cables, and these cables must be further protected from mechanical injury by either steel or wooden armor. This I have learned by sad experience to be true, even when the current is carried at a low voltage. Underground rubber-covered wires carried on glass insulators will, after a while, leak as much power as a very poorly constructed air-line, and the wires will break wherever they come under a drift. At the mine with which I am at present connected there is an installation of electric and air-driven pumps, side by side, of about the same capacity,

affording an excellent opportunity for comparison in the costs of their respective transmission-lines, 1600 ft. down a vertical shaft. The cost of the cable to supply the current to the electric pumps was some three hundred dollars more than the cost of the pipe supplying air to the compressed-air pumps. It has been stated that the cost of putting in air-pipe is greater than that of electric wiring. This also is sometimes not true, depending very much on circumstances. In the installation to which I have just referred, putting in the electric cable probably cost the most, but an exact account was not kept. An expert had to be obtained from San Francisco to do the splicing. As this could not be done either vertically or in a wet place, the cable had to be spliced before lowering down the shaft. As it was not strong enough to support its own weight, it was necessary to lash it at intervals to a wire cable as it was lowered, and afterward to cut it loose from the cable and clamp it to the shaft timbers. Unforeseen difficulties, such as the two cables becoming twisted around each other, and the fact that the hoisting engine was not strong enough to support the total weight, made the operation anything but as simple as it would seem. Now that they are both in place, if anything happens to the air-line, any miner can replace a length of pipe, but if something should get loose on a cage and rip out a piece of the cable, the consequences might be disastrous and expensive, carrying, as it does, current at 1000 volt. Many people would consider 1000 volt too high a potential for safety in a mine, and if this were reduced to 500 volt, the cable would have cost twice as much as it did.

To take up the question of loss of power in transmission; electric and air-transmission lines should be calculated in exactly the same way, that is, the size of the conductor or pipe should be in either case such that an increase in size would not save enough power to pay the interest on the added investment. Therefore, if the cost of the transmission-lines were the same in the two cases, the loss in power-transmission would be the same. As a matter of fact, it is too often the case that the superintendent or foreman 'guesses' that a four-inch line will carry it' in the case of an air-pipe, but when it comes to an electric line, about which there is something mysterious to many people, the services of an electrician are called in, and he figures the size by formula. But this state of things does not change the facts, that the loss of power in transmission should be no more in the case of compressed-air than in that of electricity, and that it costs about as much for electric-cables as it does for air-pipes. I might add that a poorly constructed electric-line will leak power as well as a poorly constructed air-line.

Arthur B. Foote.

Grass Valley, Cal., August 3.

Willow snow fences are to be tried on the Northern Pacific railway the coming winter in North Dakota. The railway plans to set out about 100,000 golden willow in the belief that they will serve better than the inflammable board snow-fences now used.
THE BLOWING-DOWN SYSTEM OF SLUICING.

By James Park.

This is a novel system of sluicing that has been successfully used for the working of wide stretches of poor alluvial ground in central Otago. Its greatest application has been in the Cromwell district, where it has been in use for over thirty years. It was first introduced by a Russian miner, and, although so long in use, is almost unknown outside of central Otago. This system can only be applied to the working of alluvial ground under the following conditions: (a) where the wash lies on a sloping bottom, having a gradient of not less than 1 in 3; (b) where the wash is shallow, that is to say, not exceeding 6 ft.; and (c) where large stones are absent, that is, stones not too large for two men to handle. In ordinary sluicing, whether 'ground-sluicing' or hydraulicking, the practice is to begin operations at the lowest part of the ground, and to work forward on the rising bottom, the main tail-race being extended as the working-face recedes. This is 'working away from home.'

In the blowing-down system the main tail-race is carried to the boundary of the ground before the sluicing is started. After the tail-race is constructed a side-race or gutter of smaller dimensions is carried along the boundary. Two strips of ground about 3 yd. wide, one on each side, are now sluiced into the gutter, beginning at the top of the slope. This is 'working home.' When the strips on each side of the gutter reach within a yard or two of the main tail-race, another gutter is carried up the slope parallel to the first, and the sluicing operation is repeated, and so on, the ground being cut away in parallel slices. Let the accompanying Fig. 1 represent the plan and profile of a piece of alluvial ground, and let the natural drainage of the land be in the direction shown by the arrow.

In the above figure, (a) is the main tail-race, (b) the side gutter, and (c) the cross-trench where the sluicing begins. The trench (c) is cut out the full width of the paddock or strip to be washed down. It need not be cut down the full depth of the wash, as the water soon excavates it to the bottom. It is merely the starting-point of the operations. The stones are thrown back and stacked on the sluiced ground as the work proceeds. The water is brought to the top part of the ground in pipes, which are extended from time to time as the ground is cut away. It is conveyed from the pipe-line to the working-face in a stout canvas pipe 7 in. diam., and provided with a nozzle at the end. The nozzle is held in the hand or rests on a movable tripod. The canvas pipe is made in convenient lengths of 18 or 20 ft. As the face recedes fresh lengths are put on, being simply telescoped into each other for two or three feet. The joint thus made becomes quite tight when the water is turned on. In some cases two paddocks are washed down at the same time, and it is claimed that this system effects a considerable saving of time, as when one gutter becomes choked with stones, sluicing can be carried on in the other. The work thus goes on continuously in one paddock or the other. In this system of working there is practically no shoveling or forking, the only manual labor involved being the stacking of the stones. Alluvial miners claim that when the jet of water is directed downhill the cleaning-up of the bottom is much more effective than when it is directed upward, as it is in ordinary hydraulicking. In the latter case the tendency of the jet is to drive the particles of gold into crevices, where they cannot be dislodged without breaking up the bottom. The canvas used is 24 in. wide, sold in bolts containing about 42 yd. With a lap of 1½ in., this width gives a hose about 7 in. diam. Two experienced miners, without assistance, sluiced away 10 acres of wash in two years. This is equal to 2½ acres per man per year. The depth of the wash varied from nothing to 5 ft., the average being 2 ft. 6 in. The blowing-down system is admirably adapted for the working of poor shallow ground that happens to rest on a bottom having the requisite slope to enable the water to carry the dirt down the side gutters into the main tail-race, where the gold is caught. It should be mentioned that it is sometimes found to be advantageous to allow a supplementary supply of water to run down the main tail-race, in order to keep it clear of debris. Further, the greater the pressure of water at the nozzle the quicker will the ground be sluiced away.

A mine may be over-ventilated until the air current has such a velocity that it stirs up dust, which in a metal mine makes the workings unhealthy, and in coal mines disseminates dust which may cause serious explosions.

MINING AND SCIENTIFIC PRESS

RECENT DEVELOPMENTS IN GOLD DREDGING

Written for the MINING AND SCIENTIFIC PRESS
By FRANK W. GRIFFS.

Although the progress made in gold dredging during the past few years has not seemed striking to the casual observer, nevertheless the results achieved are more far-reaching and solid than were those attained in the earlier days of dredging for gold. There has been no radical change in the design of the dredge itself, which is now an effective, well-balanced, reliable machine. Progress has taken place in a general improvement in essential mechanical details, together with important modifications of the gold-saving appliances. The work still to be done lies in progress along the same line of perfection of detail; for now, while most of the big parts, which long absorbed attention, are satisfactory, the effectiveness of these larger factors is still dependent upon the smaller ones. The capacity of any given dredge, and the resultant operating cost per cubic yard, is governed by the number of hours per day throughout the year that the dredge is actually digging gravel.

Great advantage has been gained by the use of special steels in the hard working and wearing-parts. The bucket-line, the most expensive wearing-part of a dredge, has been so improved by the introduction of chrome, nickel, and other special steels, that, even in the hardest digging, the bucket-bottoms will last for two and a half years. The hood of the bucket has been changed from a three-piece riveted affair to a single-piece part. This hood is made of cast-steel or cast-malleable iron with projecting rim for the bucket-lip to rest on, or of pressed-steel. The cast hood is strong, but is expensive. It is hard to fit, and excessively heavy in the larger buckets; consequently the pressed hood is generally used. An elaborate trial of the ‘three-eye’ (or three bearings for the pin) bucket has been made during the past two years, but it has not proved a marked success. Personally, I do not advocate the use of the ‘three-eye’ bucket, for two principal reasons: first, an account of the excessive strain put on the third eye, which causes the bucket to fail at this point when the pin wears; second, the change which is necessary in the upper tumbler greatly reduces the bearing-surface of the tumbler on the bucket-bottom, and further complicates the serious problem of the upper-tumbler wear.

More attention has been given to the gold-saving function of the dredge, with good results. Gravel hard to wash is most effectively treated by the revolving screen. Both the diameter and the length of the screen has been increased, and a greater amount of water, under higher pressure, is used. Small nozzles have been tried along the spray-pipe, but they are easily broken off, and are not of much practical benefit. An auxiliary force-pump, with a discharge at high pressure through two or three nozzles, independent of the main spray-pipe, would materially aid in the washing of ‘sticky’ gravel. The gold saving has always been good on a dredge, although the table-area is limited by the size of the hull, but it became a more serious problem as the capacity of the dredges kept constantly increasing, with no proportionate increase in the size of the hull. To meet this question, a double bank of tables was devised. In former practice, the fine material which passed through the screen was treated by one of two methods. First, the material dropped into a steel distributor under the screen, and was fed onto tables running at right angles to the distributor. These tables discharged into a tail-sluice, which carried the material off the stern of the dredge. Second, the material dropped into a steel tray, sloping in the same direction as the screen toward the stern. This tray discharged into another tray sloping in an opposite direction, which carried the screening back toward the bow, and emptied into launders, which distributed the material over a series of tables, which ran toward the stern. The effective table-area was limited by the height of the lower end of the screen from the deck.

A development of this second method led to the double-bank of tables, in order to get more gold-saving area. The first tray was changed so that the material from the upper screen was made to discharge directly upon a set of tables built immediately over the original set. These tables did not extend quite to the stern, but discharged over an inclined chute to the lower end of the lower tables. A further evolution of this idea led to a return to tables similar to those described under the first method, that is, the screening passed into a distributor, which extended the length of the screen, and from the distributor upon tables which ran at right angles to the screen. At the upper end of these tables, slots were cut and provided with adjustable plates, so that as much material as desired could be fed through pipes down to a second set of tables, which ran parallel to the first set, and about 4½ in. below them. These tables discharged into separate tail-sluices, one for each bank, running astern, one over the other, one being about 7 ft. higher than the other at the point of final discharge. The upper tail-sluice extends some 15 ft. farther aft than the lower. By this means the fines are carried farther back from the dredge, and are so well distributed that the sand-pump is entirely done away with.

The trend of development has been toward larger dredges, of greatly increased capacities. By this development, and also by the close attention which has been given to details in the smaller machines, the cost per yard of dredging has been materially reduced. When the dredge reached an assured capacity of one million cubic yards per year, and the cost approximated five cents per yard, it seemed that a standard had been set. It was felt that this was near to the economical limit of yardage, when the gold-saving as well as the digging was considered. But it soon became apparent that the larger and heavier the machines were, the easier they would dig hard compact gravel at less cost per yard. Then, with these larger dredges it was proved that ground which had been considered undredgable, either on account of hardness or on account of very low gold content, could be worked at a profit. Dredges with
close-connected buckets of 8 cu. ft. are now being successfully operated on the hardest ground known in dredging practice. There are also two dredges with close-connected buckets of 13 cubic feet.

The Folsom field offers a most interesting example of the progress and development of gold dredging, both with regard to the construction of the dredge and to the character of the material handled. There are two distinct channels at Folsom. The gravel of one is clean "wash," remarkably easy to dredge and to treat, as there is no clay and little sand. On the other channel, the gravel is harder than any that a dredge has ever been used upon. The deposit is deep, averaging, on Rebel Hill, from 60 to 75 ft. It is practically cemented for the first six or eight feet, and is very compact for 25 to 30 ft. The lower strata of the gravel bed are looser, and do not present any great difficulties in dredging. In common with many who examined this Rebel Hill channel, I felt that it could not be dredged except at excessive cost, and not at all without constant blasting. The problem which this ground presented was unparalleled in gold dredging. To dig gravel of such character a dredge of exceptional strength had to be designed. If the depth had been 30 ft., the question would have been serious enough, but to build a dredge with buckets of 8.5 cu. ft. capacity to dig to a depth of 70 ft., with all the excessive weight of machinery that would follow the carrying out of such a design, seemed an almost impracticable task. It was R. G. Hanford, general manager for the Folsom Development Co., who conceived the idea of using monitors to break down the first 25 or 30 ft. of ground, and by this process only the remaining 35 ft. would have to be dug. As the water-level of the pit would be 20 ft. below the surface of the ground, some means of disposing of the tailing had to be devised. It was thought this could be accomplished by building a very long stacker and by using two extraordinarily large sand-pumps. So the dredge Folsom No. 5 was built. The hull was 110 ft. long by 44 ft. 6 in. wide, by 10 ft. deep. It was specially designed to stand the heaviest digging-strains. The machinery was made almost excessively heavy. The ladder was supplied with water from a high-head centrifugal pump, driven by a 100-hp. motor. The dredge started to work in December, 1905. The results of the operations were most interesting. The monitors were a success, and broke down the bank, by undermining it near the water-level, without difficulty. The ground below water-level did not prove as hard as that above, and the heavy dredge handled it with comparative ease. However, the sand-pumps were a failure, and, as the operations of the dredge were...
entirely dependent upon them, serious complications developed. These difficulties were gradually overcome by lengthening the digging-ladder 15 ft., and by using the double-bank of tables, a feature first developed on this boat. This dredge pointed the way to a solution of the problem of digging successfully and economically the hard deep gravel of Rebel hill. This solution was achieved by dredge No. 5 of the Folsom Development Co., which began to dig gravel in March, 1908. No expense was spared to make it as effective a dredge as possible. The experience acquired in working No. 5 dredge led to a more highly satisfactory machine that is handling about 150,000 eu. yd. of gravel per month, at a cost of approximately 4½ c. per cubic yard. A general description of this dredge is as follows:

Length of hull........................................ 120 ft.
Width of hull, on water-line................................ 46 ft. 6 in.
Depth of hull............................................. 10 ft. 3 in.
Dredging-depth below water-level at 45°........ 45 ft.
Size of buckets........................................... 5½ cu. ft.
Number of buckets........................................ 86
Weight of buckets, each................................... 305 lb.
Weight of upper tumbler.................................. 20,000 lb.
Weight of lower tumbler.................................. 16,000 lb.
Weight of ladder and fittings.......................... 144,000 lb.
Dimensions of steel spud: 54 by 34 in. by 75 ft. long
Weight of steel spud....................................... 76,000 lb.
Revolving screen........................................... 7 ft. diam. 36 ft. long
Weight of revolving screen................................... 48,410 lb.

The total weight of machinery on the dredge is approximately one million pounds. In addition to this machinery-weight, the following partial list of material is used in the construction of the dredge:

<table>
<thead>
<tr>
<th>Material</th>
<th>Weight (lb.)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Truss rods and plates</td>
<td>30,000</td>
</tr>
<tr>
<td>Iron and steel</td>
<td>30,000</td>
</tr>
<tr>
<td>Nuts, bolts, and nails</td>
<td>33,000</td>
</tr>
<tr>
<td>Piping and valves</td>
<td>24,000</td>
</tr>
<tr>
<td>Total</td>
<td>181,000</td>
</tr>
</tbody>
</table>

The total weight on the dredge exceeds 1,250,000 lb., while 370,000 ft. of lumber was used in the hull.

The motor equipment of the dredge aggregates 560 hp., distributed as follows:

<table>
<thead>
<tr>
<th>Motor Type</th>
<th>HP</th>
</tr>
</thead>
<tbody>
<tr>
<td>Main digging</td>
<td>200</td>
</tr>
<tr>
<td>Main pump</td>
<td>100</td>
</tr>
<tr>
<td>Secondary pump</td>
<td>50</td>
</tr>
<tr>
<td>Winch, variable speed</td>
<td>50</td>
</tr>
<tr>
<td>Screen, variable speed</td>
<td>30</td>
</tr>
<tr>
<td>Stackier, variable speed</td>
<td>50</td>
</tr>
<tr>
<td>Monitors, two 50-hp.</td>
<td>100</td>
</tr>
</tbody>
</table>

All motors 50 hp. and over take current at 2200 volt, and all motors under 50 hp. at 440 volt. The pumps used are: main pump, one 12-in., 60-ft. head, centrifugal, direct-connected to 100-hp. motor; secondary pump, one 12-in., 30-ft. head, centrifugal, direct-connected to 50-hp. motor; pump for monitors, one 8-in. two-step, 150-ft. head, centrifugal, direct-connected to two 50-hp. motors.

The tables are of steel, of the double-bank type of construction. The tail-sluices are 4 ft. wide. The stacker is a 38-in. belt-conveyor, 142-ft. centres. Unfortunately the buckets are of the three-eye type, and are already causing wear on the upper-tumbler faces. This is a source of annoyance and delay, but is subject to correction. The main cause for delay in the operation of the dredge comes from the bowsing-lines. This seemingly insignificant point is an illustration of what was mentioned earlier in this article, namely, that the work ahead of the dredge-designer lies in the perfection of details. I venture the assertion that the capacity of the dredge has been reduced 10,000 cu. yd. per month on account of time lost in the moving and replacing of these bow-lines. At the onset ¾-in. lines were used. On account of the hard servies, they lasted only a short time. They were replaced by 1½-in. lines, which are giving fair satisfaction, but they are very cumbersome to shift. In the ease of this dredge the side-line trouble is increased on account of the high bank which is always around the dredge.

The monitors at the bow of the dredge are fitted with 2-in. nozzles. The water is furnished to them by a special 150-ft. head centrifugal pump with 10-in. suction and 8-in. discharge. This pump is direct-connected to two 50-hp. motors. The two monitors are operated at the same time, and are in use about two-thirds of the day. Care has to be exercised so that too much of the bank is not broken down at one time, for in that event the ‘cave’ would either fall so far behind the bow of the dredge that the buckets could not pick up the gravel, or so much material would have to be handled by the dredge at one setting that it would ground at the stern. The dredge does not present any difficulty in handling the tight ground, while the washing in the large screen is excellent. The double bank of tables affords ample area for saving the gold, and the system of double tail-sluices does away with sand troubles. With the exception of the wear on the upper tumbler-plates and the swing-line problem, the dredge is eminently satisfactory. When these troubles are corrected, there would seem to be no reason why it should not maintain an average capacity of 150,000 cu. yd. per month.

The development of this dredge marks a distinct forward step, by demonstrating that ground which a few years ago could not have been dredged, can now be handled with profit. In marked contrast with this hard gravel is the other deposit at Folsom, which is being worked by the ‘thirteen-foot’ dredges. This gravel is easier to work than any other deposit I know of. About two years ago the Folsom Development Co. built its No. 4 dredge, with close-connected buckets of 13 cu. ft. capacity. This machine has handled a yardage of approximately 180,000 per month, at a cost of about 3c. per cubic yard. Using this dredge as a guide, the Natoma Development Co. installed a 13-ft. dredge on adjoining ground. The Natoma No. 1 began operation on May 7, 1908, and has made a most remarkable showing. An unusually large hull was built, both to
insure flotation and to provide for a large table-area. Extra large shaking-screens are used, as no revolving screen could handle the tremendous amount of gravel that the buckets dig. As the gravel is clean, and has only a small percentage of sand, it washes easily and runs freely over the tables, which are of the double-bank type and are most efficient. This of congestion is shown by the fact that at two of the ports, Empedocle and Licata, there is absolutely no room for new warehouses or depots, while the stocks already held are enormous. The sale of sulphur at low rates for industrial purposes has been advocated, but this idea had to be abandoned, as not only difficult of control, but as contravening the agreement

lower Bank of Gold-Saving Tables on Folsom Dredge No. 6.

The Silician sulphur industry, according to the Financial Times of London, is in a difficult situation because of excessive over-production, caused by a slackening in exports, for which there appears to be no immediate prospect of alleviation. Even the good will and assistance of the Government and the efforts of the Sulphur Association seem to have been powerless to avert what looks like a serious crisis threatening the industry. Advices from Palermo state that the glut has been so great that at the end of February stocks were estimated at 573,000 metric tons, and production continued at 450,000 tons, while exports were not more than 400,000 tons. The degree with the American industry. Another more likely scheme is to sell unrefined sulphur-ore abroad as a substitute for pyrite.

BALANCES.

Written for the MINING AND SCIENTIFIC PRESS
By A. Austin and Swift Hunter.

The principle underlying the ordinary chemical and assay-balance is that of a lever of the first class, with arms of equal length, the power and weight consisting of the force exerted by gravity on the masses carried in the pans. This lever when constructed in the form of a beam of a working balance must combine certain properties in order that it may possess the requisites for accurate weighing, namely, sensitiveness and stability of poise.

By referring to a text-book on physics we find, worked out on the principle of moments, formulas which show that, in a good balance, the knife-edges from which the scale-pan is suspended must be on an exact level with the fulcrum or centre-bearing of the beam. Also, letting L = length of the balance-beam, W = weight, and D = the distance of the centre of gravity below the fulcrum, then it is shown that the deflection for a given load depends on the magnitude of the fraction \( \frac{L}{WD} \).

In order that the balance may be very sensitive, namely, with a readable deflection on very small weights, this relation of L, W, and D must be considered. The relation of L to W is such that the apparent advantage of making L large is more than offset by the increase of W. Hence balance-makers are today constructing a beam that is short and very light.

The necessity for a value D is apparent, for the sensitiveness of a balance must go hand in hand with its stability of poise. Stability of poise implies rapidity of indication and to secure the latter it is necessary that the centre of gravity of the beam be some distance below the fulcrum. A large value tends to make the balance less sensitive, so that a value for D must be chosen to give a balance of fairly quick action, leaving it still sensitive enough for the work in hand. It follows that the lighter the beam the greater can the value D be for a given sensitiveness.

The lowering of the centre of gravity of the balance increases the friction on its bearings, and calls for extreme care in the construction of knife-edges that the sensitiveness be not destroyed. A good balance for smelter-laboratory work must be sensitive and stable, and yet quick acting. The beam, though light, must be rigid enough to bear the heaviest weights used on it. To facilitate weighing, a convenient beam and pan-rest are necessary. Control of the beam may be secured by the turn of an outside thumb-screw, one action disengaging beam and pans. Or the beam may be taken from its rest by the motion of one mechanism and the pans from theirs by a different one. The one-motion release is common on button balances, the latter on analytical types.

The balance should be equipped with a suitable pointer and a graduated are to indicate its deflection. For weighing milligrams or fractions the beam is graduated, and a rider used in conjunction, which is moved back and forth by a shifter operated from without the case. Regulating-screws for changing the equilibrium and centre of gravity of the beam are required, also screw-rests for leveling the balance. The balance is usually surrounded by a glass case of a compact and convenient form to furnish suitable protection from sir-draughts, dust, and fume. Finally, as installed, the balance should show the desired grade of sensitiveness by a movement of the pointer over one-half a division of the arc under the smallest weight. Stability should be evidenced by the tendency of the pointer to invariably re-assume its original position. Balances in use around a laboratory may be divided into two classes: analytical balances and button balances.

Analytical Balances.—The common balance of this type is capable of bearing a load of 70 to 80 gm. in each pan. The finer and more expensive grades have a rated sensitiveness of \( \frac{1}{20} \) mg. Another common grade is rated as sensitive to \( \frac{1}{10} \) mg. As a rule, those operators who are using the finer balances on ordinary laboratory work have adjusted the centre of gravity of the beam so as to decrease the rated sensitiveness with a view to quicker weighings. The balance as it then stands is very stable, and because of good construction is very accurate. Certain grades of analytical work do not require as sensitive a balance as the \( \frac{1}{20} \) or \( \frac{1}{10} \) mg. type. For instance, in weighing out pulp containing a small amount of the element sought, as in colorimetric copper-work, the balance need not be sensitive under 1 mg. One gram or more of sample is taken and the copper content is perhaps only 3 or 4 mg. The amount of material taken is an index of the sensitiveness required. An assay pulp-balance weighing assay-ton lots is rated as sensitive to \( \frac{1}{4} \) or \( \frac{1}{2} \) mg. In actual use the balance is not weighing up to such a grade. An operator should keep in mind the closeness of weighing required to give the admissible error, and then keep well within the limit. In variance to a button balance, equality of arms need not be a requirement on an analytical balance. If there is a difference it can be compensated for by always weighing pulp and result on the same pan. When so weighing it is a question not of actual but of relative weight.

Button Balances.—A very sensitive balance is required for weighing gold and silver beads. The manufacturers of balances are constructing balances rated as sensitive to \( \frac{1}{500} \) mg. in order to meet the demand for an accurate balance for weighing extremely small amounts of gold. Nowadays when gold is reported in thousandths of an ounce, such a balance is required. Of course, the weighing is made on two or more assay-tons, so that few gold-buttons are weighed below \( \frac{1}{1000} \) mg. A balance of the above grade will handle a maximum weight of 10 gm. Silver or silver-gold buttons do not require as sensitive a balance as the \( \frac{1}{500} \) mg. type, nor, for that matter, does a reasonable sized gold-button, where a difference of a couple of hundredths of a milligram is allowable. The opening up of large deposits of copper-ores, with a very small gold content, has brought into prominence the demand for a balance of the \( \frac{1}{500} \) mg. type. The gold-button from an assay-ton of such ore may be one or two hundredths
of a milligram in weight, and should be weighed very closely because of the large tonnage it may represent.

Other types of button-balances are rated as sensitive to \(1/100\) mg, or \(1/200\) mg., the lowest grade being \(1/500\) mg. Portable assay-balances are usually sensitive to \(1/100\) mg. The button-balance as now constructed is a very beautiful piece of work. The beam is rarely over 5 in. long, and is made of a strong, light material, such as aluminum or some of its alloys. It is non-magnetic, and has a low coefficient of expansion, to do away with temperature-changes. The material in hangers and other parts is in keeping. A very short column is used on the most sensitive balances and they are then known as the 'non-column' type. The short-column, by decreasing the length of the pan-hangers, tends to concentrate the movable mass near its central axis, giving great stability of poise. To compensate for the short-beam a long pointer is used which plainly indicates a small beam-movement. Reading glasses may assist in reading the pointer, or for determining the reading of the rider on the graduated beam. The non-column balance may have two different styles of pointer. One kind is upright, the graduated arc being at the top of the balance-case. The other kind is an extension of the beam, and is horizontal, the graduated arc being vertical. One make of balance has no graduations on the beam, but uses a special graduated scale, independent of and behind the main beam, and by a special carrier denotes accurately the position of the rider on the main beam.

Such an independent scale allows of smaller scale-divisions. Another balance is equipped with a device known as a multiple rider. It is an attachment operated from outside the case, which places riders on a suitable support the equivalent of placing flat weights on the pans. The makers claim constancy of weights and a saving of time for the mechanism. The bearings of all types of button-balances are made of agate, and considerable skill is necessary to form the crude stone into fine knife-edges. All button-balances are equipped with fail-away panrests. Control of the balance is secured by one turn of an outside thumb-screw. The action at first releases the pans, and turning still farther sets the beam free. A button-balance should be carefully adjusted. It should be tested for sensitiveness, for stability of poise, and for equal arms. The graduations on the beam should also be tried out.

Installation, Care, and Operation of Balances.—Special precautions are necessary on installing a delicate balance. A good strong table set on a firm floor usually suffices for the foundation of an analytical balance, and such a support may answer for a button-balance. It is best to set the latter on a firm foundation of stone, concrete, or wood. A good rest may be had by cementing two 8-in. iron pipes into a solid foundation. The pipes pass free through the floor and have a heavy timber bolted firmly to their top at a working height. Unusual precautions may have to be taken on installations subject to vibrations.

There is one source of trouble that may constantly annoy an operator, and that is the tendency for a balance to become magnetized. Even so-called non-magnetic beams seem subject to this complaint under certain conditions. In some parts of the Southwest, where sandstorms are common, the static electricity generated by particles of sand striking together will incapacitate a balance for fine work for the duration of the storm. Such a condition may be overcome to a certain extent by grounding the balance with copper-wire. Matters are often made worse by an insulated base which prevents the balance from discharging. When using a balance it is best to avoid rubbering the glass base. A balance may often be discharged by pressing the fingers against the case. While the balance-room should be well lighted, it is necessary that the direct rays of the sun should be kept out. Such rays, while they may strike the balance for only a short while, will destroy its equilibrium for some time afterward. The balance-room is usually found on the north side of the laboratory. As even a temperature as possible should be maintained and any local source of heat, such as an electric light, kept at a safe distance. The room should be separate from the main laboratory, be dry and not subject to vapors or draughts. A good operator handles his balance carefully. It should be kept clean, and the cleaning up is best done after the day's work is over, as the balance has then a long period of rest until the next weighing, to assume its equilibrium. A cloth cover is kept on the balance when it is not in use.

When starting to weigh it is customary for an operator to test the balance for equilibrium, as he may for one thing have left the rider on the beam and then forgotten it. When weighing grams or half-grams on an analytical balance the usual custom is to weigh by 'no deflection,' disregarding friction and inertia. Heavier weighings, as for instance the platinum cylinders used in electrolytic copper-work, are weighed by swings. The beam is best set in motion in such a case by dropping the rider an instant upon it. Button-work is always weighed by swings. A certain system should be adhered to when weighing by swings. For example, the first swing of the pointer to the left is disregarded; the pointer then swings over to the right and that reading is noted and made to agree with the next swing of the pointer to the left. Such a system can be used only on a sensitive slow-acting balance, as otherwise the quick decrease in the length of swing would prohibit it. As it is, it implies that the true zero of the pointer is not that of the graduated arc. For testing a balance it is perhaps best to take the mean of the swings to the right and left, but in practical weighing such procedure is too slow. In determining the weight of a substance a certain system of testing the weights is used by all operators.

Weights.—To weigh accurately it is necessary to have accurate weights. Riders and weights are often used which are not of true weight, hence the necessity for checking all weights before using. Button-balance weights must be standard, and those in use on analytical balances likewise. As weighings on the analytical type may be relative, it follows that
if the set of weights agree one with another it suffices, but it precludes the use of weights from another set unless all are standard. An assay-office should possess a set of standard weights, and such a set should be used for no purpose other than comparison with working-weights. For designated fees sets of weights or individual weights will be accurately weighed, classified or made standard by the Government Bureau of Standards in Washington. Manufacturers of weights will send weights to the Bureau at the request of a buyer, and they often keep on hand such Government standardized weights in boxes sealed with the Bureau’s seal to save purchasers time and bother. The manner of keeping standards in the Bureau, and the method of checking and classifying the weights submitted, is very interesting. It is all to be found in Bureau Circular No. 3, of the U. S. Bureau of Standards, Department of Commerce and Labor. A tolerance on weights is allowed by the Government according to the class and size. On assay weights of 1/10 to 1/2 mg, a tolerance of 1/100 mg. is permissible, and so on up to a weight of 20 kg., where 200 mg. is permitted. Actual weights are determined very closely by the Bureau, being reported to 1/1000 mg. on tenths of milligram weights. The Bureau requires the weights to be of suitable material and after standardization specifies careful treatment to preserve constancy.

Very accurate weights and riders may be purchased from the makers. They are sold in the smaller sizes under classes, the best class showing the smallest deviation from the true weight. First-class riders from 1/2 to 12 mg. are guaranteed to be within ± 1/1000 mg. of the marked weight. The lower, or commercial class of the same riders, may deviate ± 1/1000 mg. Small flat weights are not so accurate. Shapes of weights in use agree very closely, with the exception of those adapted to the multiple-rider balance. Weights below 1 gm. are usually made of platinum, and above 1 gm. of brass. Platinum keeps a very constant weight with proper handling. Brass weights may show a tendency to vary, and for that reason when weighing platinum cylinders, where a number may be required, the same brass weights should be used on all weighings of the same cylinder.

The largest vertical gas-engine in the world was recently started in the plant of the Castner-Kellner Alkali Co., Ltd., Runcorn, England. It was furnished by the British Westinghouse Co., and is capable of developing 1000 hp. No water cooling is used for any of the moving parts. Forced lubrication is used throughout, the oil pumps being in duplicate, and these can be examined and the oil sieves changed while the engine is in operation. All valves are positively operated by means of straight push rods actuated directly from the cam shaft. The engine is direct-connected to a generator supplied by the same company.

Evidence from the mounds of Ohio shows that the copper deposits of Michigan were known to and worked by the mound-builders.

### BRITISH COLUMBIA MINERAL PRODUCTION DURING 1907.

The annual report for 1907 of the minister of mines of British Columbia has recently been issued. The value of the mineral products of the Province for the year 1907 is greater than that of any preceding year, amounting to $25,882,560, showing an increase over the last year of $902,014, equivalent to an increase of 3.6%, and is 15.2% greater than the output of 1905, and 36.3% greater than that of 1904.

An analysis of the returns shows that this increase is due to the greater tonnage of low-grade ore mined in the Boundary district, and also to an increased tonnage from the collieries, both in coal and coke. As regards quantities, the production of placer-gold last year was the smallest reported since 1898; that of vein-gold was the lowest since 1900. Silver was less than in any year since 1895, and lead less than in any year since 1904. The copper output was greater than that of any previous year since 1906. The coal output in 1907 was the largest ever made; coke had only been exceeded once, namely, in 1905.

The ore mined in the Province during the year 1907, exclusive of coal, was 1,804,114 tons. This was produced by the various districts in the following proportions: Boundary, 65.1% of total; Rossland, 15.8; Coast, 4.7; Fort Steele, M. D., 8.6; all other districts, 5.8. The number of mines from which shipments were made in 1907 was 147; but of these only 72 shipped more than 100 tons each; 36 in excess of 1000 tons each.

The production for the year, divided as to the several minerals, is as follows:

<table>
<thead>
<tr>
<th>Mineral</th>
<th>Quantity</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Gold, placer</td>
<td>oz.</td>
<td>$528,000</td>
</tr>
<tr>
<td>Gold, lode</td>
<td>oz.</td>
<td>196,179</td>
</tr>
<tr>
<td>Silver</td>
<td>oz.</td>
<td>2,745,448</td>
</tr>
<tr>
<td>Lead</td>
<td>lb.</td>
<td>47,788,703</td>
</tr>
<tr>
<td>Copper</td>
<td>lb.</td>
<td>40,832,720</td>
</tr>
<tr>
<td>Total metalliferous</td>
<td></td>
<td>$17,044,847</td>
</tr>
<tr>
<td>Coal</td>
<td>long tons</td>
<td>1,800,067</td>
</tr>
<tr>
<td>Coke</td>
<td>long tons</td>
<td>222,913</td>

<tr>
<td>Building materials</td>
<td></td>
<td>1,300,000</td>
</tr>
<tr>
<td>Total values</td>
<td></td>
<td>$25,882,560</td>
</tr>
</tbody>
</table>

A comparison shows that British Columbia produced more gold, copper, and lead than all the rest of the Canadian Dominion combined, but that Ontario has surpassed her in the production of silver. The Province produced no nickel and practically no iron.

The total mineral production of British Columbia from the first record to and including 1907 is as follows:

<table>
<thead>
<tr>
<th>Mineral</th>
<th>Quantity</th>
</tr>
</thead>
<tbody>
<tr>
<td>Gold, placer</td>
<td>$65,549,198</td>
</tr>
<tr>
<td>Gold, lode</td>
<td>45,070,717</td>
</tr>
<tr>

THROUGH THE BOLIVIAN HIGHLANDS.

Written for the Mining and Scientific Press
By E. P. Mathewson.

Few people realize that an overcoat is a useful article on board ship at the equator. The Humboldt current follows the west coast of South America from Tierra del Fuego to the equator, where it turns west. It plays an important part in the regulation of the weather conditions, particularly as to rainfall. The prevailing winds are from the west. The moisture-laden clouds from that direction meet the cold air above the Humboldt current and precipitate their burden in the ocean. The high range of the Andes prevents rain clouds reaching the west coast from the east, so there exists a strip of land that is practically rainless from Coquimbo, Chile, to Guayaquil, Ecuador, varying in width from 100 to 300 miles, and in elevation from sea-level to 15,000 ft. above tide. Occasionally a fertile valley is seen running from the coast to the Andes, where some stream works its way from the snow-capped mountains to the sea. In these valleys semi-tropical vegetation is encountered, and it is from these that the famous long-staple Peruvian cotton comes. One of the most arid provinces of Chile is Antofagasta, with a capital city of the same name, known chiefly in this country in college song. From Antofagasta there extends a line of 28-in. gauge railway to Oruro in Bolivia. This was, until recently, the only railway extending into that Republic. It was built by the Cia. Huancha de Bolivia with capital advanced by an English syndicate, which syndicate owned the railway but rented it from the date of its completion until a few years ago to the company that built it. The Huancha de Bolivia Co. is to Bolivia what the Anaconda Copper Mining Co. is to the State of Montana, and more. It is the one great enterprise of the country. It owns the silver mines at Pulacayo, Bolivia.

Antofagasta is the chief shipping point for all Bolivian products. Its chief industries at the time of my visit in 1901, were the smelting of the Pulacayo and other ores at the smelters, known as the Playa Blanca & Templeman, the refining of nitrate of soda at one establishment, and the forwarding of merchandise from and to Bolivia. Since that time the nitrate deposits have been prospected extensively on the Pampa across the lowest or first coast range, with the result that there are now 13 oficinas for nitrate, the port is congested with traffic, the new port of Co- loso, a few miles south, has been opened, and the old and much better port of Mejillones has been re-opened and connected with Antofagasta by a line of railway. Antofagasta is now as great a nitrate port as Iquique, 40 sailing vessels or 'wind-jammers' frequently loading and unloading at one time, in addition to numerous steamers. It is a dry town in one sense, only one rain worthy the name having fallen in two years.

The railway equipment is somewhat miscellaneous. The locomotives are mostly of European make, and the passenger coaches are American. Most of the freight cars are no larger than a good-sized over- wagon, holding only 5 metric tons. Cars recently purchased have brought the maximum load up to 20 tons. No air-brakes were in use, but a peculiar form of hand-brake, in which the brakeman turned a crank, was employed instead. The road is up hill all the way to Bolivia, and a good stiff grade it is most of the way. Passing a little canyon in the first range of hills the train reaches the first pampa. At Pampa Central are indications of nitrate mining.

The genial superintendent of the mines invited the travelers to lunch, and as the train had only 150 miles to make during the first day there was plenty of time to enjoy his bounty with vino rojo or blanco del pais (native red or white wine), according to taste. Calama was reached by nightfall. Trains on this railway, and many others in South America, do not stop out after dark. Each station and yard is fenced in and gates are closed across the tracks and the trains are locked in for the night. Calama is a small settlement in an oasis in the desert.

There is no running water between Antofagasta and Calama. The river Loa, rising in the Andes not many miles away, flows through the town, and a few miles beyond sinks in the sand and disappears forever. To supply water for Antofagasta an 8-in. pipeline is laid alongside the railway from the source of the Loa to Antofagasta, a distance of about 200 miles. The difference in elevation between the highest point and sea-level is nearly 15,000 ft. Consequently relief tanks have been put in along the line...
at frequent intervals to reduce the pressure. These tanks are open on top and consequently the dust of the desert, mixed with salt and borate of lime and some nitrate of soda, blows into them, contaminating the water, so that it has to be distilled before using. Sea water is still the only water supply in many places along the coast of Chile. It is distilled, of course, for domestic use, but is used 'straight' in the boilers, zinc plates being hung in the boilers to prevent corrosion.

But to return to Calama: There are a few acres of alfalfa in the vicinity of the town, and the crop saves the lives of the animals that are driven across the desert of Atacama from the Argentine Republic to the coast. Calama was also, up to the time of which I write, the shipping point for Chuquicamata copper ores. Now a spur of the railway is extended to Chuquicamata.

The name Chuquicamata is said to be derived from Indian words meaning 'here is gold.' Some concentrating or gold panning was done here by the Indians in the early days. Later they discovered the copper ore, atacamite, a volatile oxichloride of copper, of brilliant green color. The surface rock is greatly shattered, and in the cracks were deposited crystals of the atacamite and also sulphates of copper and iron.

The aborigines used stone hammers bound to willow handles with rawhide for breaking down the rock; for wedges willow branches were employed, and rawhide punched full of holes served for sieves. The material that passed through the sieves was their ore; all the rest was counted as waste.

A very valuable find from an archaeological point of view was made at Chuquicamata about 1899. In opening a mine the mummified remains of an Indian were found where he had been killed by a 'squeeze' of rock. The face and trunk were badly smashed, but the rest of the body was perfect.

The modern system of separating the atacamite is by crushing and screening in trommels. The resulting fine stuff or 'clamos' are sometimes concentrated on Willey tables near Calama, and the product, containing 40% copper, is shipped to Swansea, where it is made into blister stone. There was, at the time of my visit, a quantity of copper sulphate ore shipped to Antofagasta and treated there with water slightly acidified with $\text{H}_2\text{SO}_4$, and then precipitated on scrap-iron as metallic copper. A small modern smelting plant had been erected near Calama and run for a time on the sulphide ores which were beginning to come in about 400 feet below the surface.

Perhaps the nearness of the volcanoes, San Pedro and San Pablo, 16 miles east, one of which is constantly emitting thin clouds of vapor, may account for the shattered rock of Chuquicamata. Earthquakes are frequent and somewhat severe. There are no 'sky-scrappers' to increase the disaster, but a one-story stone section-house near the mountain collapsed during one earthquake in 1901, injuring all the occupants. The shock was felt distinctly 200 miles away, in Antofagasta. A wealthy Bolivian on his way in a special train from Oruro to Antofagasta was near the volcanoes when the shock occurred.

The train-men found boulders on the track, so the train was started back toward the last station, but the ballast, consisting largely of pumice stone, had been shaken out so that the party had to wait for 24 hours until a relief expedition arrived.

The Chilean miner is one of the best single-hand drillers in the world, but, like most Latin-Americans, he needs the incentive of a fixed task or a contract to call forth his best efforts. He is a stoutly built fellow with fine chest and big arms, having a good deal of the Araucanian Indian blood in his veins. The Araucanians were never completely conquered by the Spaniards.

Leaving Chuquicamata the road passes close by the volcanoes of San Pedro and San Pablo. The plain round about the volcanoes shows the result of many outpourings of lava and volcanic hail. There are great deposits of sulphur on the sides of the volcanoes, and one enterprising Spaniard has a monopoly to mine or quarry the sulphur on all the volcanoes in Chile. He has a small refinery in Antofagasta and sells his product for the manufacture of powder at the nitrate oficinas.

The next important point is the borax lake of Ascotan, 12,000 feet above sea-level. This looks like a lake covered with ice and snow. The Borax Consolidated, Ltd., owns the lake, and the method of obtaining the borate of lime is to use pick and shovel after removing a few inches of the top deposit. The borate of lime thus obtained contains considerable moisture. It is therefore piled up in sharp conical piles to dry, then sacked and trammeled to the railway station, where it is shipped to Antofagasta for further drying in muffles, using coal for fuel. It is then ready for shipment to Europe.

At the station where the borate of lime is shipped we saw our first vicuña. These yellow-brown relatives of the camel are peculiar. There are four varieties of the camel family to be found in the Andes. The vicuña, and guanaco, which are wild animals, and the llama and alpaca, which are domesticated.

There are three principal native fuels in Bolivia, yareta, a resinous moss mostly found below the surface of the ground, which is cut up into blocks like aldobes; laguna or llama dung; and turba or peat. Analyses of these fuels are given below:

\begin{align*}
\text{Volatile} & \quad \text{Fixed} \\
\text{Yareta (dry)} & \quad 67.79 \quad 17.12 \quad 15.09 \\
\text{Tequia} & \quad 41.94 \quad 10.35 \quad 47.71 \\
\text{Turba, A.} & \quad 51.74 \quad 18.22 \quad 30.04 \\
\text{Turba, B.} & \quad 52.96 \quad 21.42 \quad 25.62 \\
\end{align*}

The next important station is Ollague, at the foot of a smoking volcano of the same name, near the western boundary of Bolivia. It is about 12,000 ft. above sea-level, and stands on the pampa, a vast plain or table-land with the main range of the Andes on the east and a lesser range on the west. The peaks of the Andes are like cones, staking up 17,000 to 20,000 ft. toward heaven. All the higher peaks are permanently snow-capped. At dusk the train arrives at Uyuni, the junction point for Puno and Huanchaca.

\textit{(To be Continued.)}
VOLCANIC WATERS.

BY J. H. HASTINGS.

*The origin of the watery vapors of vulcanism has always been an object of interest and speculation to the seismologist, and as theories of the genetic origin of ore deposits have of late years been pretty well narrowed down to the expiring forces of plutonic action, the same question has had a lively interest for mining engineers and geologists, as is well shown by the discussions on the subject in the Transactions of the American Institute of Mining Engineers. The important part taken by volcanic emanations in the origin of pegmatites and quartz-veins, and their latent power to concentrate into useful deposits such scattered gold as occurs in the Hartsgel granite, make a discussion of their derivation but a natural third and final step.

It is conceded that enormous amounts of vapor accompany vulcanism, though perhaps we are apt to forget that steam has 1700 times the volume of water, besides which the column seen over Vesuvius and other volcanoes is greatly mixed with air; the immensity of such volumes compared with solids and liquids is shown by the experiment of Gautier, who, by heating dissected granite to 100° C., evolved from it gases 20 times, and steam 90 times, its own volume. Dana appraised the average amount of water left in ordinary rocks as 2.5 per cent.

T. M. Read estimated that the Mississippi river carries to the sea annually 150,000,000 tons of rock material. If these Mississippi sediments, as deposited, contained 20% water, it would be 600,000,000 cu. ft., or 4,500,000,000 American gallons, annually. Allowing the vapor suspended over a volcanic cone to be mixed with 80% air, this amount of water converted into steam would replenish anew, every 9 min., a column 15,000 ft. high, 2000 ft. diam. at the base, and 10,000 ft. at the top. Read’s estimate is only half of the amount given, and is more recent and probably correct one.

In the present papers, however, it is not intended to dispute estimates of the vapors accompanying vulcanism, or what part of it springs from primeval hydrogen and oxygen locked within the earth’s interior, or from vadose or oceanic waters. It is simply my purpose to ask whether any of the water buried deeply with oceanic sediments can make its way to the eons of molten material. An immense amount of water is buried with sediments, and it probably stays there until removed by the rise of the isotherm of either a gentle rise or a comparatively sudden one, accompanying the movement. Experience in examining teaches that water will stay in interstitial spaces until displaced by another substance or exhausted into a vacuum. Hence, the spaces left in compacted sediments will be full of water, unless the isotherm rises as the sediments are laid down and expels it. The gentle action of heat is aided by the expansion and loss of viscosity of warmed water; the latter quality is said to be about one-fifth at 100° C. of what it is at 0° Centi-grade.

Though enormous pressures can be figured on every square inch of buried sediments, the evidence of compression in them, except where there has been movement, is not great. The pulpy matter of rotted sigillaria, etc., has been crushed to perhaps 1% of the original volume, and converted into bituminous coal; but even this coal is not a very dense material to preserve its form over areas of many square miles when buried under thousands of feet of rock subsequent to the Carboniferous age. It takes extreme pressure and heat to make anthracite.

As to the rise of the isotherm from normal conductivity or pressure, there is little light, except theoretical. The continents show increased temperature with depth, but they are areas of considerable movement—elevation—which in itself would be accompanied with heat, and what remains may be in part residual. The same might be said of the ocean bottoms, substituting a movement of depression. If the heat-conductivity in the earth be judged by its radiation it is very slight. It has been described as small, but still measurable. The abyssal ocean waters are just above freezing-point. This low temperature has been thought to be due to rapid extrac- tion of the earth’s heat from the oceanic beds by conductivity because of their greater density than the continents, for instance, and the rapidity with which the waters absorb the heat and quickly distribute it through convection. Again, it has been ascribed to the immense polar currents moving slowly southward along the bottom. It is hard to find any warmth in the ocean except that due to the rays of the sun. Chamberlin and Salisbury,1 citing P. G. Tait’s Heat and A. Daniell’s Physics assert that these authors respectively place the earth’s loss of heat in 100,000,000 years at 18° F. and 81° F. for the whole body of the planet.

Do the sediments as deposited contain much water, and do interstitial spaces survive compression of the beds? J. D. Dana thought that “sedimentary beds contain their maximum of moisture when laid down; and with this, though situated at the bottom of a trough, they have still laid quietly.” Not much has been said of late by geologists about water carried down in sedimentary beds as they are deposited. T. Sterry Hunt and others referred to it, and thought that some eruptive rocks were formed from saturated sedimentaries. Perhaps the only emphatic recent article bearing on the subject is by F. H. King,2 which not only treats of the amount of water the sediments might once have held, but presents a study of them after elevation, and shows their storage capacity up to the present time. The following passages are from his work: (P. 69) ** * * ** sandstones lying below drainage outlets may contain water up to 38% of their volume. * * * The Dakota sandstone, for example, stretching from the foothills of the Rocky Mountains eastward beneath the plains of the two Dakotas, Nebraska, and Kansas, apparently in one nearly or quite continuous sheet, may be likened to a submerged inland sea.

or lake, for wherever this formation lies beneath the zone of saturation it carries within itself from 15 to 38 ft. of water on the level for every 100 ft. in thickness of the sandstone, and from it water may be drawn wherever it lies close enough to the surface to be reached by wells. The Potsdam sandstone is a formation of much wider distribution than the Dakota, and in southern Minnesota, Wisconsin, Illinois, and Iowa it has a measured thickness of 500 to 1000 ft., all lying beneath the surface of saturation, so that in this great bed there has been stored a quantity of water equal to a sheet not less than 10 to 38 ft. deep for each 100 ft. of thickness, and 500 ft. of this water-bearing rock may store the equivalent of an inland submerged sea having a mean depth of 50 to 190 ft. of water. Ordinary clay with sand held 25% water, and very fine sand 17%. Marble held very little, 0.25%, or a column of 5000 ft. held 30 ft. of water. Experiments with sediments laid down in a cylinder showed that the water flowed downward or laterally through the sediments and up through a rubber tube discharging 6 in. above the top of the column of water and sediments; it was not denied that some water, as the sediments were deposited, may have come up vertically through them, but the lateral and downward outlet seemed to be the line of least resistance. (P. 80)

"We have no quantitative measure of the amount of compression which, under the conditions of natural sedimentation, takes place where beds of shale and limestone are formed. Such consolidation of sediments and displacement of water as may have taken place by the ordinary processes of sedimentation, unaided by other agencies, must still have left large volumes of enclosed water to be deeply buried in districts like the Appalachian region, where, during Paleozoic time, if the estimate of Dana be accepted, an aggregate subsidence and sedimentation of 36,000 ft. must have taken place."

When these materials were laid down the pore-space was about 33%, or 12,000 ft. of water. But these rocks have since been greatly consolidated, highly metamorphosed and crystallized, perhaps making the pore-space much less than 33%, so that if they were now full of water a very large amount would have been displaced in the past. The same thing has occurred in the interior region of our continent. (P. 81) "These large volumes of water which have been carried beneath the earth's crust as a phase of the process of sedimentation must in part have re-appeared at the surface in one place or another, and there must of necessity be an underflow of the entrapped sedimentary waters from beneath the ocean toward the land." Such subsidence produces increased temperature of the material, and resultant flow of water.

"Poisnille found that water at a temperature of 45° C. flowed 2.5 times as fast as water at 5° C. under otherwise like conditions. G. F. Becker says quartz weighs 165 lb. per cu. ft., and quartz sand well shaken down 120 lb. per cu. ft.; therefore the sand contains 27.3% of interstitial space. This com-

pares very well with the natural sand-beds and sand-stones of the California quicksilver mines.

Do sediments subside until they are at an immense depth below the ocean bottoms? The general opinion of geologists, in answer to this question, is here given. J. W. Dawson* wrote that 10,000 to 20,000 ft. of sediments in Nova Scotia and the Eastern United States were laid down in shallow seas—that is, the bottom of the seas subsided as they were deposited. In the Alps the sediments which accumulated between the Permian and late Cretaceous periods are thought to exceed 50,000 ft., all accumulated in shallow water. Dana says:© "Consequently, when these last layers of the Paleozoic in the Appalachian regions were at the ocean's level, the Potsdam beds, though once also at the surface, were about seven miles below; for this is the thickness of the strata that intervene; seven miles of subsidence had, therefore, taken place in that region during the progress of the Paleozoic ages." Clarence King judged that the subsidence in the Rocky Mountains amounted to 60,000 ft. S. F. Emmons¹ thought that from early Cambrian to early Carboniferous age the great accumulation of beds in the longitude of the Wasatch mountains amounted to 15,000 to 20,000 ft., not strictly without movement of elevation and depression, but without great disturbance. Bailey Willis says: "In the Appalachian trough opportunity for maximum sedimentation during the Paleozoic was afforded by the profound subsidence of an area in New York, Pennsylvania, Virginia, and Ohio. At Mauch Chunk the total thickness is approximately 30,000 ft." R. T. Hill,² describing the Beaumont oil-fields, mentions 25,000 ft. of marine sediments, from Cambrian to recent times, minus the Devonian, and says they are "tilted steeply in the mountainous areas, and are nearly horizontal in the plains." (P. 400) "Of the 22,000 ft. of sedimentaries in the Texas section, all but 2000 ft. or less are unconsolidated clays and sands."

These examples might be multiplied. Chamberlin and Salisbury in their new 'Geology,' touch the other side of the question. They allow that subsidence has gone on in epi-continental (shallow bordering) and mediterranean (deep inland) seas, the inland sea of North America, for instance; and do not deny that it occurs elsewhere. But think that errors in computation may have been sometimes made. For instance, suppose sediments deposited conformably on the abyssal floor of an ocean, which slopes 2° until a depth of four miles is reached, whence the floor goes off flat, but the sediments keep on piling up conformably at 2° dip till they are built out 200 miles from shore. An observer at the shore end, taking the angle of dip of the first bed laid down, and prolonging it for the 200 miles, which on this dip would take it far below the ocean bottom, and then calculating the distance at right angles to the dip from the bottom of this first sediment to the top

*Some salient points to the Science of the Earth.
of the last one laid down, would get 7 miles, instead of 4, the real depth of the ocean and the true thickness of the sediments. It is certainly plausible that protracting a dip for 200 miles might lead to error. If it were protracted 5 miles the discrepancy would be 0.15 mile. Another instance is given of a lake 100 miles wide, with sides sloping at 3° to a depth of 1000 ft., whence it remained flat. The sediments were then laid down conformably at an angle of 3°. The observer takes the angle of dip at the shore and projects it at 3° for 50 miles, getting so far below the bottom of the 1000-ft. lake that his computation at right angles to the 3° dip, at the end of the 50 miles, gives a depth of 13,800 ft., instead of 1000 ft. These layers of sediment, diagonal to the depth of the lake, would strike bottom in about 3 miles, that is, if any of the beds were followed from the outcrop down the 3° dip for that distance, they would be found ending in a truncated edge against the lake bottom, so that their horizontal length would be little more than the supposed thickness, whereas the Appalachian relations, as computed, are in horizontal extent 20 times or more their thickness.

Another important question is whether the continental shores are lines of weakness, so that there is a possibility of the enclosed waters of the sediments passing from them into the land areas. While there are certain parts of the present continents and also oceanic depths which are thought to have existed since the dawn of geologic history, it is well known that almost all of the inner area of North America has been occupied by a mediterranean sea, so that tremendous thicknesses of sediments have been laid down in Arizona, Utah, Idaho, and British Columbia; that the ancient sea of Tethys stretched from Spain to the eastern coast of Asia; that the Arctic was once much larger than now; and also that the southern continents, Africa, Australia, and South America, were apparently closely connected. These facts have been worked out by careful research by such men as Dawson, Dana, and others on our shores and elsewhere. The facts have been lately collated by B. Willis, who says, in effect, 9 that uplands of erosion and lowlands of aggradation are commonly joined by a monoclinal flexure, or a normal fault. Great horizontal movements are shown in the schistose structure of once deep-seated rocks. These movements crowded the continental elements together, as is evidenced by the shortening of the Appalachian sediments from their original horizontal breadth, from 168 miles to 60 miles. Lately, however, the narrowing has been put at 35 to 45 miles. Much may depend, perhaps, on the locality of the section observed. That oceanic areas might be denser than continental, probably appeared early to a number of minds and was mentioned by some, but E. P. Dutton was the first to formulate with emphasis the theory of 'isostacy,' which predicates that the sectors of the oceans and continents are in equilibrium, the depressions of the one and the elevations of the other equalizing the specific gravity of the two. Willis calls the oceans and continents positive and negative elements, and specifies the line of contact between them as a zone of weakness, especially favorable for the development of intrusive and extrusive bodies. It may be interesting for a moment to glance at B. K. Emerson's 10 statement of the theory of a tetrahedral earth as postulated by its originator, W. L. Green, a Honolulu merchant: 'The sphere of all solids contains the greatest volume under a given surface, the tetrahedron the least volume under the same surface. The solid spherical crust of the earth, then, collapsing upon its plastic interior, would tend toward the tetrahedral form as the one which would co-ordinate the greatest diminution of the interior with the least change of the surface.' The continents are shown to be situated more or less on the protuberances of the tetrahedron. Emerson says the tendency for the earth to take such a form may be allowed to exist and would be in evidence where not balanced by other forces. However, approached by geologic theory, I think it is generally acknowledged that continental shores are broad lines of weakness; furthermore, that the general arrangement of volcanoes, as taught by Dana and others, is symmetrical with these lines. This does not preclude volcanic action far away from the coast. If the elevation of the continents is due to the thrust of the debris oceanic beds, large distances may be insignificant. Neither does it preclude vulcanism under the ocean. It matters not that there are quiescent areas, where under this law vulcanism might be expected to be active. Many have observed the marked feature of critical epochs in the world's history, that there have been geological periods of slow subsidence and elevation without much vulcanism.

The depth of vulcanism may be great, but the depth of earthquake centers, which we associate with movements in the earth's crust (faulting), originally considered as great (even from 30 to 55 miles by Mallet), has of late years been restricted to 5, 8, or 12 miles, which brings it not so much below the sedimental range.

Are the waters of vulcanism similar to those included in sediments? Since it is not supposed that these waters are exclusively derived from the sediments, they may be greatly modified mixtures as we see them. Prestwich says: 11 'Not only are almost all the elements of sea-water found in the gases and deposits of fumaroles, with the exception of magnesium which has become fixed in the lava, but seaweet itself is often found in lava or is deposited on its surface.' The Challenger expedition Reports give the salts of sea-water as roughly: sodium chloride, 78; magnesium chloride, 11; magnesium sulphate, 5; calcium sulphate, 4; potassium sulphate, 2; calcium carbonate, 0.25; magnesium bromide, 0.25%. The total quantity of salts is fairly uniform at 3.5% of the water. The salts vary; sometimes the bromides are more plentiful, and stronium, iodine, fluorine, glaucinite, etc., are found.

MINE REPORTS

ZINC CORPORATION, LTD.

The Mining World, of London, reports proceedings of interest at the recent ordinary meeting of the stockholders of the Zinc Corporation, Ltd., from which the following statement by H. C. Hoover is abstracted:

The ore at Broken Hill contains lead, zinc, and silver. The mining companies there crush the ore to the fineness of sand and extract from it, by water concentration, about 60 to 70% of the lead and silver content. The residue from this treatment, which is sent to the dump contains, therefore, practically the whole of the zinc and between 30 and 40% of the original lead and silver content in the ore. The Zinc Corporation already bought and paid for about a million tons of these residue dumps, and has the right to buy about a million tons more. The residue being treated at the present time is from the Block 10 mine, and averages about 20% zinc, about 8 oz. silver, and about 5 or 6% lead. The residue from these old dumps is taken by the Corporation's own railway and dumped into large bins underneath the track at the works. From here the material is carried by a belt-conveyor to bins at the top of the hill. Thereafter, the residue is automatically fed into the smelting furnaces and grinding pans, to be reduced to further fineness. After this re-grinding, the material passes to agitators, in which it is mixed with oil and sulphuric acid, and is drawn from the agitators through Elinore vacuum machines, and the zinc, lead, and silver are concentrated, the product being mixed zinc, lead, and silver concentrate. This completes the first stage of the process. The second stage is the separation of the lead from the zinc in this mixed concentrate, making two concentrates, one in which zinc predominates and one in which lead is the principal content. The reason for this second treatment lies in the terms upon which the concentrate has to be sold. The zinc smelters will pay only for lead in the concentrate in excess of 8%, and will only have the value of the lead. Likewise, they will only pay 1 1/2d. per lb. for the silver over 5 oz. per ton, and they will pay for the zinc content at the average price of zinc over the year of purchase, less the cost of shipment to Europe, smelting charges, loss in recovery, and profits on smelting. Nor will the lead smelter pay for zinc in the lead concentrate—in fact, a penalty is imposed if there be more than 15% zinc present.

In order to give reliable figures it is necessary to assume prices, as, for example, of zinc £19 5s. per ton, and lead £12 10s. Now, the average price of zinc for six years has been £23, and lead £13 16s. But we are now in the midst of a great depression, and the price of zinc is today £18 5s., and lead £12 17s. For the first half of the year it averaged £20 10s., so that even if it averages only £18 for the balance of the year, the yield thus lost would be £3 5s per ton of the sell-on the year's average. By the end of this year the tide of depression will probably have turned. The average content of this mixed concentrate is about 45% zinc, 12% lead, and 16 oz. silver. If sold, we get the material at this stage to the zinc smelters, we should get but little pay for the lead and silver content, so that our great objective has been to devise a secondary treatment to extract as much lead and silver as possible from the mixed concentrate and sell it as a lead concentrate. This has a second very great advantage, as, by taking away the lead, we increase the proportion of zinc in the zinc concentrate and it becomes more valuable. Therefore we have devised, after exhaustive investigation, a method by which we take the mixed concentrate and re-treat it to separate a lead concentrate. In this process the lead will still give us to the £19 5s. of this sell-on the year's average. This means that on the present output, if we sold the mixed concentrate as its stands, we should realize about £5000 less than we do realize by first separating a portion of the lead, so that there can be no question as to the £5000 of this secondary treatment, to which practically all the profit is due. There are several aspects of the treatment which have an important bearing on the future of the Company. On the basis of last week's output we are earning a net sum of £7000 per month above all expenses, out of which about £2000 should be set aside for cost of tailing worked up, or a net amount of about £4000 per month, or £48,000 per annum profit.

This profit is capable of very important increase from many directions. First, the working expenses are always high at the initial stages of a new plant. Although the plant is absolutely mechanical, and no human hands touch the material from the beginning to the end, it takes months to train men and organize them to the best advantage. In this business men have to be trained from the ground up, as this is entirely a new business in which no men of experience can be obtained. Next, we have to pay for our water, and we shall soon be prepared to bring in our own supply for at least part of the year. Expenses at the start were about 14s. per ton, and for the month of June were reduced to 12s. 3d. per ton. I believe it will be ultimately decreased to 8s. per ton, which would give an additional profit of over £2500 per month. Second, the mill is treating about 12,000 tons per month. By gradually strengthening the lower limits of the plant the tonnage can be increased to 20,000 tons per month. This would mean an increase in working profit by £500 to £1000 per month. Third, we are obtaining an extraction of over 88% of the original zinc content of the residue. This shows an increase from about 72% the first month. We have obtained in systematic experimental work as high as 92% extraction of the zinc, so that we may take minor improvements here. An additional 4% recovery would augment profits by £500 per month. Fourth, the improvement in re-treatment of the mixed lead and zinc concentrate is one where very important possibilities lie. The lead extraction from the original residue at present averages about 70%. This, in the first instance, is mixed with the zinc in the Elmore concentrate, but we can get out of the mixed concentrate over £15 per ton, which is equal to an actual extraction into final salable lead of only 17c. of the lead in the original material. In experimental work we averaged a recovery of 40% of the original lead, instead of 17c, as above. We hope eventually to duplicate this in regular operation of the plant. If we do so the increased profit from the extra lead and the further increased purity of the zinc would, on the present scale, add about 50c. per ton to the metal value between £2500 and £3000 per annum. We have, therefore, a possible increase of the present profit from redution of expenses of £2500 per month, from increased zinc extraction £500, from increased tonnage £500, and from increased lead extraction £2500, or a total of £1000 per month, or £70,000 per annum, and this without increased price of metal. To do this, or something approaching it, we shall need to lay out £70,000 or £8000.

To recapitulate, at the present moment we are earning a profit above the cost of the material we treat, and on present low prices of metals, of about £48,000 per year. If we succeed in these technical improvements, we shall raise it to over £100,000 per annum. I cannot guarantee that we shall accomplish this. We have past results for periods, and every week since we started have shown some improvement. The other great element of certain expansion for the Company's profits is a return of metal prices to normal. The average price of zinc over six years is £23, of lead £13 16s. For the calculation given zinc has been taken at £19 5s., and lead at the present price of £12 10s. On the results already attained our profits would have been greater by £5000 per month, or £60,000 per annum had normal prices prevailed. If we accomplish the technical improvement outlined above, and also have the happy coincidence of normal prices of metal, the profits of the Company with this mill will be over £150,000 per annum, instead of £48,000 at present.

The Jeffrey Mine, Co. Columbiana, Ohio, has recently issued Bulletin No. 25, the title of which is 'Handling Coal and Ores,' and Bulletin No. 16, describing the Jeffrey A-5 electric rotary drill.
ORE GRINDING MILL.—No. 893,535. Charles D. McLure, St. Louis, Missouri.

In an ore-grinding mill, a low conical base, a trough formed around the edge thereof, a series of segmental plates removably positioned on top of the base and extending from the trough to the apex of the base, upwardly extending lugs formed integral with the upper ends of the plates, a retaining ring arranged around the lugs, and a plurality of grinding wheels arranged to travel in the trough.

In an apparatus of the character described, the combination of a hollow pivot, a filter wheel rotatably supported thereon, a circular series of filter units carried by said filter wheel, means for supplying to said filter units the material to be filtered, means for drawing the filtered liquid from said units comprising conduits leading from said pivot severally to the interiors of said units, a pipe leading to the filter wheel, and means whereby, in the rotation of said wheel, said conduits are connected in succession to said pipe, substantially as described.

In combination with an ore disintegrating apparatus, a receptacle in which the disintegration takes place, parts forming an upwardly extending outflow channel of uniform cross-sectional area and also forming a secondary channel intersecting said outflow channel in a substantially horizontal direction, and means for providing a supply of liquid to said receptacle at a uniform rate.
Decisions Relating to Mining.

Specially reported for the MINING AND SCIENTIFIC PRESS.

ENTERING MINE AGAINST CAUTION—INTENT.

The statutes of some of the States make it unlawful for a miner to enter any place in a mine against caution, or to disobey orders, or to do any other act whereby the lives or health of persons or the security of the mine would be in danger. In a prosecution for the violation of such a statute, it was held that the intent to endanger life or property was not an element of the offense; that the intentional doing of an act with knowledge that in so doing life or property would be endangered, was the gist of the action. The caution as used in the statute was held to mean simply to give notice of, or warn against, danger.

Koppala v. State (Wyo.), 53 Pac. 662, Feb., '08.

RECORDING CERTIFICATE OF MINING CLAIMS.

The statute of Nevada providing for the recording of certificates of location of mining claims, was held to be directory only; and where the doing of the acts required to make a valid location was fully proved by other testimony, it was said that the location would not be invalidated by a failure to record the certificate thereof.

Wales v. Davies, 156 Fed. 667, Dec., '07.

FORFEITURE OF CLAIM—BURDEN OF PROOF.

Where a party seeks to establish the forfeiture of a mining claim the burden of proof is upon him, and in order to establish such forfeiture, the proof must be clear and convincing that the owner has failed to comply with the law.

Wales v. Davies, 156 Fed. 667, Dec., '07.

MINING CLAIM OF CORPORATION—WORK BY STOCKHOLDER.

A stockholder in a mining corporation is said to have such a beneficial interest in the corporate property as any work done by him on the unpatented claims of the corporation could be counted as representative work, and if sufficient in amount and done at the proper time, would prevent a forfeiture of the claim.

Wales v. Davies, 156 Fed. 667, Dec., '07.

CHARACTER OF ASSESSMENT WORK REQUIRED.

The United States statute requires that not less than one hundred dollars' worth of labor shall be performed or improvements made on a mining claim during each year; but the statute does not specify the kind or character of the labor. It was accordingly held that labor expended in extracting ore from the claim was within the statutory requirements. It is only when labor is performed outside of the boundaries of the claim that its character becomes material, and in that case it must tend to the development or improvement of the claim, or it will not count.

Wales v. Davies, 156 Fed. 667, Dec., '07.

SALE OF MINE—BROKER'S COMMISSION.

A mining corporation was liable for the services of a broker employed by its manager and treasurer, where it received the price demanded for its property and executed a conveyance with the presumed knowledge of the broker's services. This was said to be within the rule that a principal cannot ratify the act of an agent's act favoring to his benefit and reject that portion to his injury.

Dillard v. Olalla Mining Co. (Ore.), 94 Pac. 966, Apr., '08.

CONTRACT OF SALE OF MINE—SPECIFIC PERFORMANCE.

A contract for the sale of a mining claim provided that the purchaser should furnish continuous employment to the seller at the mine at a specified rate per day beginning on a certain date, and terminating when the contract should terminate. The court refused to decree specific performance of the contract on the ground that there was a clear remedy at law in damages for its breach.

Mallory v. Globe Boston Copper Mining Co. (Ariz.), 94 Pac. 1116, March, '08.

Books Received.

Mr. Bowie, who appeals by the title of his new book to the agriculturist, is of course Mr. Bowie the mining engineer. In fact, he is only bringing his wide knowledge and experience in hydraulic mining and the problems of water-storage and distribution connected therewith, to bear in another direction. But he returns the same old book of Mr. Wailes. He has written a book which will aid the mining engineer as much as the farmer. When he discusses the losses due to evaporation and seepage, flow of water in ditches, water-measurement, development of water in arid and semi-arid districts, flow of wells, pump-duty where large volumes of water are to be lifted, earth tanks, and the like, he is dealing with subjects that are the same as those dealt with in the development of the natural resources of the country. His book is a mine engineer's book of the highest order.

A complete summary of the methods of analysis for tin, antimony, and arsenic does not exist than this clear-cut statement of Mr. Parry. He has the faculty of brief exposition, and so his 143 pages contain an extraordinary amount of valuable information. The methods of analysis described are with special reference to those complicated products which present difficulties not described in most textbooks, such as drosses, scrap, fume, precipitate, slag, spiege, and the like. The methods given embrace all the common metals, but particular stress is laid on tin and antimony. An exceedingly useful feature of the book is the skeleton outline of methods of analysis applicable to a large number of substances, methods of testing chemicals, making and testing standard solutions, and a warning page of errors to avoid: all given in the most readily usable form. It will be a valuable assistant at any chemist's elbow.

Commercial Paragraphs.

The Alexander Pipe Co. reports the receipt of a large order for 2-in. pipe from the Pacific Telephone & Telegraph Company.

Carl A. Allen and C. Lohmier Colburn have formed a partnership for the practice of mining engineering, with offices at 614 Ideal Bldg., Denver.

Atkins, Keoll & Co., San Francisco, report that they have recently sold two carloads of Amoconda fireclay bricks to the Noble Electric Steel Co., for use in the electric melting plant at Herolt, California.

The Wagner Electric Mfg. Co. has recently made an initial shipment of water-cooled power-transformers, forming part of an ultimate equipment of 36 transformers, aggregating 10,530 kw., for the U. S. Reclamation Service in connection with the Salt river, Arizona, irrigation project.

Balke & Brandt Co., 943 N. Main street, Los Angeles, are selling second-hand and slightly used machinery under a guarantee. Every piece is overhauled and thoroughly tested in their own plant. Mr. Balke is a gasoline-engine expert and the founder of the business, and Mr. Brandt was for 12 years chief mechanical engineer for the Baker Iron Works.

F. W. Braun announce that its San Francisco branch house will in the future be operated under the firm name of Braun-Keest-Hemann Co. G. Knecht and R. Heinmann, who have been with the house for the last 15 years, will have the controlling management of the new company. The Los Angeles house will retain the firm name of F. W. Braun.
EDITORIAL.

SYSTEM is the machine of omnipotence. By it men may wield power far and near; may be in touch with the private secretary across the table, and with thepeon dumping slag below the smelter. A recent correspondent remarked that it was impracticable to personally supervise the details of operations, save in a small plant. That is not true. The successful manager is he who wisely delegates authority, and once delegated, never withdraws it, but who does actually know and touch the details and the men, down to the very least.

THE Mexican Government is growing less lenient as time goes on. Not many years ago holders of concessions were granted indulgences with lavish generosity. Today they must perform their obligations or stand aside for those who will. The iron rule applies even to Mr. Harriman, whereby the people may feel that an even chance for all is to be the Mexican policy in future. Mr. Harriman obtained a valuable concession for a railroad down the west coast, through Sonora and Sinaloa, and thence across the mountains through Tepic to the city of Guadalajara. This road, known as the Cananea, Rio Yaqui & Pacific, has been constructed from Guaymas to Culiacan, a distance of 549 miles. The concession was to have expired in 1910. This was extended to 1912. Finally Mr. Harriman sought an additional three years' grace, and the answer from Chapultepec is 'nay!' The result is a sudden increase of activity in railroad-building through one of the finest stretches of virgin territory in North America.

The Lawson Circus.

It was P. T. Barnum who announced that the world likes to be hoaxed. He had the effrontery to say so in his autobiography which he used to sell outside the circus-tent, while he invited the hoax-loving multitude to pay another fee to enter and see the 'What is it?' and the 'Cardiff giant' which Major Pond had manufactured to turn a desirable penny. Barnum was a true humorist; he set no traps for the unwary; he promised nothing that he failed to deliver; he aroused no hopes that he did not fulfill. But he played on human credulity; he re-discovered that the world was willing to pay for its credulity, which was known as far back as the days of the Delphic oracle and before; he laughed at his dupes openly and then duped them again—for a consideration. Thus he became the prince of showmen, and his memory is held dear enough to exite a certain species of reverence in those who experienced the delection of gaping at his meaningless 'wonders.' So we feel that Lawson is taking a rather saerd name lightly when he appeals to the shade
of Barnum in support of his recent antics. Barnum never held out the hope that his patrons who paid 50 cents for a ticket of admission would escape with $3.50 in their pockets. The gate-money was gone forever, and there was plenty of pink lemonade, peanuts, and popcorn-balls inside to deplete the reserve-fund of the unwary swain. Barnum never appealed to the ministers—never! He was no pharisee. He knew he was a sinner, and that the ministers would hurl anathema at him the Sunday before he came to town, and urge repentance upon the flock the Sunday after. Barnum never invited the school-teachers. He knew they dared not come. In short, he was just a jolly showman, extending a cordial welcome to all, sure that fun was a good thing, and quite unwilling to spoil it with an ethical dissertation. But Lawson plays upon a complicated and dangerous instrument, which is as the orchestra of the dance-hall to the homely banjo in the hands of the genial showman of earlier and simpler days. He offers stock in a preposterous corporation with a preposterous capitalization of a billion dollars! He offers it cheap; it will return 700 per cent profit “unless lost in the stock market.” Think of Barnum suggesting that you could possibly lose anything! You paid your money and saw the show! That was what you came for. But you don’t see the show in Lawson’s circus. You merely get harangued ad infinitum et ad nauseam as to why the program was changed and why the competitor next door is having all the fun. The pitiful thing about it is that just now Lawson is reaping the aftermath of a field which had been harvested of a crop of righteous indignation against monopoly. It is the class-passion he is exploiting now. The trust is the natural enemy of the people, says Mr. Roosevelt. Down with the trusts! cry the laboring-men. On every hand the protest is made, and then comes Lawson, the tool of the “system,” depending on the credulity of the people to furnish him with money to pretend to whip the desperoils. The tide that even Roosevelt has not yet succeeded in stemming—forsooth Lawson will convert into controllable force to undo its evil effects. “Like cures like” is the principle of the homeopaths, but Lawson is administering the medicine in the copious fashion of the old-time bottle-drenching allopaths. We fear the dose is too large. Trinity and Yukon are to be redeemed, along with other stocks of unpleasant memory. It is so preposterous that we marvel that it really is true that the people will pay for all this advertising, but they probably will, because they are just socialistic enough at heart to rejoice in being dominated, and to be afraid of the virility of individual initiative which would protect their independence.

Relation of Placer-Gold to Schists.

OLD-PLACERS have from time immemorial been assumed to indicate the probable proximity of important veins. This theory has been cherished in the face of preponderant evidence to the contrary, just as the popular superstitious belief in the increase of richness in a vein with depth remains unshaken, although the experience gained from mining has demonstrated the absence of any universal law governing the vertical distribution of metals within a lode. The most striking fact concerning the great gold mines of the world is their disconnection with important placers. As a counterpart to this, the great placer-deposits have seldom been supplemented by discoveries of veins which have developed into rich mines. It is true that in the California ‘gold fields’ a few properties have been operated at a profit, ad to very considerable depths. It is also noteworthy that the gold-content, though low, has been quite remarkably uniform, and has continued practically undiminished as far as exploration has extended downward upon the deposit. The Black Hills of south Dakota afford another example of the same phenomenon. Instances are numerous all over the world. The rich placers of California have been derived from a region of schists and slates enclosing innumerable stringers of quartz, very generally containing gold in small amounts, and often showing nuggets of considerable size. These veins are hard and not subject to alteration, and are often ‘frozen’ to the enclosing schist. The mine of the region has been developed where such quartz-masses have been of exceptional size, and where there has been a grouping of many quartz-stringers within a narrow zone. The rich placers have resulted from the erosion of the country, followed by stream-concentration of the detached gold. Such has been the case in California, in the Black Hills, in the famous hoc of Colombia, in Minas Geraes, Brazil, in the plateau around Cuyabá, Brazil, in Siberia, and in Alaska. In the Yukon Territory Mr. J. B. Tyrrell has made an attempt to approximate the volume of ore from which have been gathered the famous placer of the Klondike district. He shows an erosion, subsequent to the last elevation of the region, from an altitude of 3500 to the present general level of 2500 feet. The removal of these 900 feet of sediments, in which, with multitudinous gold-bearing quartz-stringers, over an area of 800 square miles, represents a volume of 136 cubic miles, equal to 1,600,000,000,000 tons of rock. On the basis of 10,000,000 ounces of gold concentrated into the Klondike placers, Mr. Tyrrell deduces an original average content for the entire mass of eroded schist of only 0.003 grain of gold, equivalent to a value of 0.013 cent per ton. Algure closely approximating this was reached by Sedoro Wolff for the schists from which, in like manner, were derived the rich placer of the Santiago River, in Ecuador.

The occurrence of minute quantities of gold in the marine silts around New Zealand was shown some years ago by Dr. Do. Other investigators have proved similar precipitation of gold in shale-forming marine deposits in various parts of the world. The segregation of this gold along with quartz-cementation occurring in late periods, induced by metamorphic processes, explains the very uniform distribution of that metal, while the resistance of the quartz to alteration explains the failure of the gold to be chemically concentrated downward in advance of the erosion of the region. The great gold veins represent mineralogical complex deposits along fis-

The tide that even Roosevelt has not yet succeeded in stemming—for- sooth Lawson will convert into controllable force to undo its evil effects. ‘Like eures like’ is the principle of the homeopathics, but Lawson is adminis- tering the medicine in the copious fashion of the old-time bottle-drenching allopathics. We fear the dose is too large. Trinity and Yukon are to be redeemed along with other stocks of unpleasant memory. It is so preposterous that we marvel that it really is true that the people will pay for all this advertising, but they probably will, because they are just socialistic enough at heart to rejoice in being dominated, and to be afraid of the virility of individual initiative which would protect their independence.

Relation of Placer-Gold to Schists.

OLD-PLACERS have from time immemorial been assumed to indicate the probable proximity of important veins. This theory has been cherished in the face of preponderent evidence to the contrary, just as the popular superstitious belief in the increase of richness in a vein with depth remains unshaken, although the experiences gained from mining has demonstrated the absence of any universal law governing the vertical distribution of metals within a lode. The most striking fact concern- ing the great gold mines of the world is their disconnection with important placers. As a counter- part to this, the great placer-deposits have seldom been supplemented by discoveries of veins which have developed into rich mines. It is true that in the California ‘gold belt’ a few properties have been operated at a profit, and to very considerable depths. It is also noteworthy that the gold-content, though low, has been quite remarkably uniform, and has continued practically undiminished as far as exploi- tation has extended downward upon the deposit. The Black Hills of South Dakota afford another example of the same phenomenon. Instances are numeruous all over the world. The rich placers of California have been derived from a region of schists and slates enclosing innumerable stringers of quartz, very generally containing gold in small amounts, and often showing nuggets of considerable size. These veins are hard, are not subject to alteration, and are often ‘frozen’ to the enclosing schist. The mines of the region have been developed where such quartz-masses have been of exceptional size, and where there has been a grouping of many quartz-stringers within a narrow zone. The rich placers have resulted from the erosion of the country, fol- lowed by stream-concentration of the detached gold. Such has been the case in California, in the Black Hills, in the famous Chocó of Colombia, in Minas Geraes, Brazil, in the plateau around Cuyabá, Brazil, in Siberia, and in Alaska. In the Yukon Territory Mr. J. B. Tyrrell has made an attempt to approxi- mate the volume of rock from which have been gath- ered the famous placers of the Klondike district. He shows an erosion, subsequent to the last elevation of the region, from an altitude of 3500 to the present general level of 2600 feet. The removal of these 300 feet of schists, with their multitudinous quartz-stringers, over an area of 800 square miles, represents a volume of 136 cubic miles, equal to 1,600,000,000,000 tons of rock. On the basis of 10,000,000 ounces of gold concentrated into the Klond- IKE placers, Mr. Tyrrell deduces an original aver- age content for the entire mass of eroded schist of only 0.003 grain of gold, equivalent to a value of 0.033 cent per ton. A figure closely approximating this was reached by Teodoro Wolff for the schists from which, in like manner, were derived the rich placers of the Santiago river, in Ecuador.

The occurrence of minute quantities of gold in the marine silts around New Zealand was shown some years ago by Dr. Don. Other investigators have proved similar precipitation of gold in shale-forming marine deposits in various parts of the world. The segregation of this gold along with quartz-cementa- tion occurring in later periods, induced by meta- morphic processes, explains the very uniform distri- bution of that metal, while the resistance of the quartz to alteration explains the failure of the gold to be chemically concentrated downward in advance of the erosion of the region. The great gold-veins represent mineralogically complex deposits along fis-
sures, shear-zones, or other lines of small resistance, mechanically or chemically. Bases and acids are plentiful, and alteration proceeds easily and rapidly. Thus the erosion can rarely keep pace with the concentration of the precious metal downward along the lode. These are striking facts, well known to engineers, but not fully appreciated by the prospector and that portion of the public which inclines to an interest in mining.

A Tariff on Zinc Ores.

NEWS from southwestern Missouri has not revealed a happy state of mind round about Joplin for many months. The zinc producers have suffered heavily from the collapse in price. There are no important new demands for zinc emerging periodically, as happens in the case of copper, to give sudden stimulus to both price and production. The absence of vast deposits which would enable one corporation to assume a dominant position in the market is another factor in the zinc situation that sets it apart from those metals in which speculation may seriously influence the market quotations.

Finally, the large number of small deposits capable of being worked at a profit has prevented control of the industry by a trust, despite several ineffectual efforts to accomplish such an end. A further interesting feature of the zinc industry is that comparatively few mines have been willing to venture upon the reduction of their own ores, for reasons flowing naturally from the conditions explained above. The consequences have been on the one side to divide the miners and the smelters into distinct camps with selfish interests tending ever to create distrust, and on the other side zinc quotations have been less subject to artificial influences than those of any other metal, unless it may be lead. Its price is thus a superior measure of prosperity or depression in the business world. Spelter gradually advanced with the upward sweep of all commodities until March 1907, when it touched 6.837 cents per pound. The lessening of demand, as reflected in the price after that month, is interesting in retrospect. The price followed a steep unbroken decline to September; rallied a trifle in October; and sunk to 4.254 cents in December. Since then it has varied between that figure and 4.83 cents. At those prices many mines in the Missouri field have been obliged to close.

In the heyday of booming industry, when the zinc mines were able to sell all the ore they could produce at such prices as had seldom been heard of before, it occasioned small concern that large quantities of 'calamine' were being imported from Mexico free of duty. This movement began in 1905, and at that time met with a protest from the Missouri miners. The contention of the Kansas smelters that calamine was only a trade name embracing the oxidized ores of zinc, both carbonate and silicate, was fully sustained by the Board of General Appraisers. It matters not that modern mineralogists have limited the name to the hydrous silicate; the Board of General Appraisers is empowered with authority in the matter of definitions which no mere dictionary-maker may gainsay, whatever he may allege on etymological grounds. In this case the fanciful application by mediaeval writers of the name of a mythical Phoenician hero to a mineral of zinc, proves nothing for either party, and the ancient usage of zinc smelters is entirely in line with the understanding of the term held by the importers of ore. Thus a protective tariff, by inadvertently leaving on the free-list an antique trade name of rather indefinite signification has thereby actually protected the manufacturer, while the producer of the raw material gets the worst of it. The Mexican ores, entered as 'calamine,' consist mainly of the carbonate, and such oxidized products require no roasting. The consequent saving over the cost of treating the zinc-blende of the Mississippi valley is enough to admit of settling with the Mexican shipper on the basis of five cents for spelter at St. Louis, even when the market quotations are down to 4.5 cents or lower. This circumstance has converted Southwest Missouri into a high-tariff community, and a so-called non-partisan Zinc Ore Tariff Club has been organized and will maintain an active propaganda to educate the people to the need of specific legislation which shall exclude foreign zinc ores of every kind. Meanwhile the producers are still fighting for a reversal of the decision of the Board of General Appraisers by the Supreme Court, and furthermore have been seeking to obtain a classification of zinc-blende by the Treasury Department as 'metallic mineral substance in a crude state,' within the meaning of the Dingley Act, which would then subject it to a duty of 20 per cent ad valorem. Neither effort to obtain classification favoring the miners is at all likely to succeed. The time-honored usage of the word 'calamine' is in accord with the construction put upon it by the appraisers, and 'metallic' can hardly be construed to usurp the function of the term 'metaliferous.'

The remedy for the miners is manifestly along the lines of new legislation, as proposed by the Zinc Ore Tariff Club. The case is clear and strong. As the law stands the smelter may utilize it to his advantage, which, as a rational being, engaged in business and not in charitable efforts, he steadily and honorably does. If the law shall prohibit importation, then spelter must advance in price, and the consumer must pay the difference. This also is conclusive. It must likewise be reasonable and desirable. High prices for the consumer have made boom times. A protected iron and steel industry, a protected lead industry, a protected leather industry, protected industry, in short, must be excellent, since it has so long met with the endorsement of those who pay for it. But, granting the truth of it, let us at least be consistent and not make times harder by keeping down the price of zinc when a little crumb of a comfortable cent or two would bring so much happiness to Joplin. Seriously, we should be logical. Let us protect, or not protect; one or the other. As the case stands our sympathy goes out to the neglected Missourian.

General Mining News.

ARIZONA.

COCHISE COUNTY.

With the completion of the enormous pumps which the Tombstone Co., is now installing on the 1600-ft. level in the Tombstone mines, the pumping equipment there will have a capacity of 10,000,000 gal. every 24 hr.—As a result of the recent visit of the Thibaud stockholders in the Santa Theresa to their properties, a few miles south of Douglas, the building of a mill is contemplated. Meanwhile, until this is definitely determined upon, the shipment of ore to the smelter has been discontinued.

GILA COUNTY.

Conditions have improved at the Old Dominion and the cost of producing copper has been considerably reduced, so that with a rising metal market, Old Dominion should soon be in a position to renew the payment of dividends. The regular development work, which includes the sinking of three shafts, was continued last week, and a large tonnage of ore of excellent grade was hoisted. The sulphide ore shipped from Dalton, Cal., is giving very good satisfaction. It runs 48% iron, 28% sulphur, 2.5% copper, and 6% silicate. Five furnaces continue in blast and are turning out about 120,000 lb. of copper every 24 hr. The Company has contracted for a large amount of coke from the Phelps-Dodge ovens at Dawson, New Mexico, and shipments will soon begin to arrive.—The Miami Copper Co. has resumed sinking the Red Springs shaft and is still extending the drifts and cross-cuts on the 470-ft. level and adding to the ore in sight.—The work of cutting the station at 450-ft. level in the Eureka shaft of the Arizona Commercial will soon be finished and connection made with the 900-ft. drift from the Black Hawk incline-shaft. Another 200-hp. boiler has been erected at the Eureka shaft and pipe for the steam column has been received.

MARICOPA COUNTY.

The Octave Gold Mining Co. will build a 650-hp. electric power plant on the Holland land, at Wickenburg. The machinery has been ordered and will arrive within 30 days. In the meantime the buildings are to be built and everything rushed ready for operation. The Octave company will sell a part of the power, using only 500 hp. itself. O. A. Knox will have charge of the construction.

MOHAVE COUNTY.

The new gasoline hoist has been placed on the Golconda mine, in Union basin and the work of sinking below the present level will soon be under way.—It is reported that a sale has been made of the Midnight mine, at Chloride, and that a payment was made this week. The Midnight mine is owned by St. Charles Bros., and is said to be one of the largest copper bearing veins in the north part of the Wallapai district.—It is reported that the hoist on the Champion mine, near Cerbat, will be moved to the New London property and used in hoisting ore. The owner, J. D. Godshall, has made arrangements with the Needles smelter to test the ore. The New London and other mines in the same group are among the best silver-gold properties in the State.—J. W. Marshall recently sold one-half interest in his Noonday mining claim, at Chloride, to H. M. Holloway, of Turman, Iowa. The Noonday is an extension of the old Arastura mine, owned by Steve Smith, and which at one time was a big producer of high-grade ore.

PIMA COUNTY.

A rich strike in the Santa Rita has made it necessary to install a big concentrator, and the machinery is on the ground. The mine is about 46 miles from Tucson and is considered a very rich property.

YUMA COUNTY.

R. P. Felipe Ortez & Ramon Villa have disposed of a one-sixteenth interest in their group of seven claims in the Castle Dome district, for use in money in developing their very promising prospects.—In Cunningham pass, Tom Carrigan has acquired an interest in a group of eleven claims, giving Walter Fleming and Julius Morell $10,000 in cash and 150,000 shares in the New Signal Co., which is to take over the holdings.

CALIFORNIA.

CALIFORNIA.

A report of a rich strike comes from the Saratoga mine, about a mile and a half east of Glencoe. It is said the ore assays over $75 per ton in gold and comes from a vein between two and three feet wide. The property includes a mill-site and water under a 200-ft. head.

MARINA COUNTY.

The Excelsior mine, near Sugar Pine, has been bonded to James E. Conde, of Arastraville, for 18 months, the consideration being $15,000. By the terms of the contract Mr. Conde is to begin work within 60 days and to pay 25% of the gross extraction, which royalty will apply on the purchase price. The Excelsior has a record production of $423,810 from June 13, 1862, to November 25, 1866. The ore was crushed in an eight-stamp mill, the stamps of which weighed only 450 pounds.

NEVADA COUNTY.

(Special Correspondence).—The North Star Mines Co. has purchased a large Plymouth freight automobile to haul supplies to the mines. It is the first of its kind to be used here.—The compressor at the Kenosha mine blew up last Monday, causing a suspension of work at the mine for a few days.—Engineers are surveying the Campbell ditch, which supplies the Blue Point mine with water, and the work of enlarging it will start in a few days.—Several men have been added to the working force at the Brunswick. Conditions are improving in the mine.—The Sweet Briar M. Co. is installing a hoist and other machinery at its property, near North San Juan. Extensive developments are planned.—F. H. Delaney and associates have bonded the St. Elmo mine to Nevada mining men headed by S. Granzer, of Sparks. The property will be worked through the Yankee tunnel. Mr. Granzer is superintendent.—Harry Overman has resigned his position as superintendent of the Ancho mine and has been succeeded by Austin H. Hart. Mr. Overman goes to Honduras in the interest of Eastern mining men.—A good body of ore has been struck in the lower adit at the Magnet mine. An air-compressor is being installed to facilitate work on an enlarged scale.

Placer County.

Bob Waugh and associates have gone to Canada Hill to do the assessment work on their Knob Hill group of claims.—The management of the Peckham Hill has ordered lumber for a mill and blacksmith shop. The boiler of the Esperanza mine, near Greenwood, has been purchased and will be set up at the Peckham Hill, and work at the Southern Cross property has been temporarily stopped on account of shortage of water.

San Bernardino County.

Work has been started on the 600-ft. adit which H. R. Ziartz has driven to the Sundown property, at Hart, recently purchased from Warren Foster. The adit is 6 by 6 ft., and will be rushed with two shifts. It is also planned to sink a 500-ft. shaft.—There has been a decided change at the Hart & Hilt adit during the past week, the soft talc formation becoming more oxidized, while colors are now obtained in greater quantity than for some time. The unusually soft ground has been penetrated for over 30 ft., and the change now appearing in the face of the tunnel is indicative of the near approach of the orebody.

San Diego County.

The Escondido Mine Development Co. has acquired the claims of the Amsco Co., consisting of 129 acres near Escon-
dido, and will begin immediately operating the property. There is already a 22-ft. shaft on the property, and this will be sunk to a greater depth immediately.—J. H. Retcliffe will start work soon on a claim which he owns at the foot of Little Tercete mountain. A number of Chana Vista men are interested.

SHASTA COUNTY.

The Black Tom Mines Co., owning the famous Niagara mine in the French Gulch district, has begun active operations with a force of about twelve men, which will be added to as fast as places can be made for them. Machinery for a 10-stamp mill has been ordered and will be erected as soon as it can be. K. H. Seibel will have charge of the plant—The smelter at Coran is practically complete, except for the concrete foundations of the converters. A large force of men are now rushing that part of the work.—A. J. Mike of the French Gulch district has secured a preliminary injunction against the Dunsie Mining Co. It restrains the Dunsie company from running the tailing of its mill over the plaintiff's placer claims. Damages are alleged to the extent of $10,000.—The Clear creek dredge, run by Cheney & Co., and constructed last year at a cost of $125,000, was burned to the ground a week ago with an insurance of $40,000. It is to be immediately rebuilt. It is conceded by mining men that know anything about conditions, that the Horsetown gravel beds where this dredge is operating will easily warrant a reconstruction of the dredge.

SISKIYOU COUNTY.

It is reported that A. M. Bixby has found ore on Lucky creek, only a mile from Forest, which assays over $32,000 per ton in gold.—Robert Duree, of San Francisco, has recently re-located the old Gardner vein, near Poker Flat, and will proceed to prospect the vein as soon as possible.—The Alaska Mining Co., at Pike City, has recently let a contract to sink its shaft 300 ft. deeper. Oswald & Oats have the contract and are working four shifts.—P. G. Fyndie has been appointed superintendent of the Alleghany mine at Balsam Flat, to take the place of W. W. Tiner.

COLORADO.

CLEAR CREEK COUNTY.

(Special Correspondence.)—One of the richest gold strikes in the history of this district has been made on the Hoery claims, on Alpine Mtn., across the gulch from Grifith Mtn. The discovery was made in the breast of the adit, 350 ft. from the entrance. The ore carries free gold and assays run as high as $15,000 per ton. The strike is 3 to 3 in. wide, the ground having been opened for 20 ft. Considerable amounts of the quartz and gold were found in the vicinity of the vein, and a number of claims have been staked off. The townsite is to be named after the owner, L. Hoery, of Georgetown, is the owner. This is the one拾 forty claim, is being developed by the owner, H. Davenport. Recently a small streak of gold-bearing rock was found, and from seven pounds that were reduced by an assayer, three buttons worth $60 were obtained. The ore carries free gold and the owner is now driving the adit in the hope of catching a good-sized streak. A body of ore has been uncovered on the Sporting Times mine, owned and operated by A. H. Colbain. The strike was made in driving on the Sporting Times vein at its junction with the Moore vein. After opening the ground for 25 ft., a crevice 3 ft. wide was showing, while 2 ft. of almost solid mineral is exposed. Leases at work on the Moore vein are following a streak of smelting ore from 6 to 8 in. wide that mills from $69 to $65 per ton in gold, silver, and lead.—A contract was awarded this week to William Collins for furnishing 400 sets of timbers to be delivered at the Scepter adit, the portal of which is on the Georgetown side of Democrat Mtn. The entire works are to be placed in condition for starting the development, which is to be put under way at once. The strike made a few weeks ago in the breast of the adit is coming up to expectations. The streak is showing for 80 ft. and is from 6 to 12 in. wide. Stopping has been started and a fair tonnage of ore is being mined. The adit is being driven steadily forward and within 220 ft. the heading will cut directly under the Sunburst workings from which a heavy production was made a few years ago. The Aster-Stewart M. & M. Co., operating this property, has notified all lessors that there will be no renewal with the expiration of their contracts, as it is proposed to do all work on company account. S. McKirahan is resident superintendent.—From 50 to 60 tons of concentrate is being sold weekly by the Burleigh M. & L. Co., operating the Pelican mill under lease. The product is not classed, but it has been found that better results are obtained, the material being worked as an average of 10 per cent. from the mill has a capacity of 250 tons for each 24 hours, two tramways being kept in operation in the delivery of the ore to the bins.—A shipment of five tons of smelting ore was made this week from the lease being operated by Anderson & Co., in the upper workings of the Seven-Thirty, and for six days' work the operators realized the sum of $1740, after paying royalty, smelting, and transportation charges. It is expected that a production of from $15,000 to $18,000 will be made monthly. The drift has been extended for 60 ft., and there remains 72 ft. of ground to be prospected.—R. C. Patterson has taken a lease on the Fairhill mill-site and dumps, a short distance above Georgetown. There is a large amount of material available and tests are now being made for the purpose of ascertaining the best method of treatment. shipments will be made directly to the various custom mills, and in the event the expected saving of metals is effected, a small concentrating plant is to be constructed.—Work is to be resumed shortly on the Blue Bird group of patented claims, Democrat Mtn. This property was formerly a good producer, but has lain in idleness for over two years. The Blue Bird vein is the eastern extension of the Pau Rock vein, and Miller & Jacobs have sold their leases on the Wheeling vein to the Waldorf Metals Co., which recently took over the majority of the holdings of the Waldorf M. & M. Co. The Waldorf Metals Co. has started work in earnest, and within another week a force of from 60 to 70 men will be at work. D. F. Sprossie is manager.—As soon as the connection between the Seven-Thirty shaft and the raise from the west Phillips drift, of the Burleigh adit, has been made, a number of people holding privileges on the Phillips vein will resume work. Hancock & Co. were compelled to close down owing to interference with the work in the raise, shipments having been in order for more than a year. The orebody is from 2 to 3 ft. wide, a part of which is of a milling grade.—Operations have been continued on the Continental adit, and the adit is being driven forward and as soon as it is advanced 400 ft. leases will be offered blocks of ground. Shipments are being maintained from the mine by Rathole & Co., operating under lease. D. Kennedy, of Georgetown, is manager.

Georgetown, August 15.

SAN JUAN COUNTY.

The Snow Flake is to be re-opened under a lease held by C. W. Kling—B. B. Slick and W. R. Hyde, of Boise, Idaho, have started work on the ten claims which compose the Sutton group, preparatory to installing a compressed-air plant with which they will drive an adit along the Denver lead and cross-cuts to the Sutton.
the Esmeralda property, in Maggic gulch. Men will be put to work immediately cleaning out the mine and getting it in condition for active work.—The Contention mill has recently made a test run on a lot of ore from the Champion mine. It is said that if the results are satisfactory a mill will be erected by the Ross M. & M. Co.—The Iowa and the Tiger mines are to be operated by a leasing company composed mainly of Silverton people, headed by Otto Mears. The mill was badly damaged by a snow slide last winter and since then neither the mines nor mill have been operated. Work will be started immediately.

SUMMIT COUNTY.

A. W. Moon, of Denver, is to start work immediately on a new dredging proposition near Breckenridge. He will put a large force of men to work, equip the plant with electricity and buy all the latest and most complete machinery. He has obtained some valuable ground which he says he can be worked successfully during all seasons of the year.—Work on the North American and Mary Verna, at Frisco, was resumed this week, after a suspension for a few months. These adits now penetrate the mountains to a distance of about 2,000 ft. each.—The Wire Patch Co. is planning to push the lower adit of the mine farther into the hill and build a raise to the upper working. This would give them enough ore to run their new mill at full capacity. About 30 men are at present employed at the Wire Patch.—The Pennsylvania mine, at Argenta, will build a new mill to replace the one now in use. Electric power from the Summit plant, at Dillon, will be used. W. B. LeWald is manager.

TELLER COUNTY.

E. J. White, who has a lease on the Gold Bond, will make his first shipment soon. The ore is being hoisted through the Sweet shaft.—McCaffiell and associates, operating on one of the blocks of the Straton's Independence have opened up a body of high-grade ore. There are several sets of lessees operating on the property, all of whom are in ore and shipping. Four sets of lessees are operating on or near the surface and are mining a smelting grade of ore with small expense. During the month of July about 40 cars were shipped from the property with an average value of from $35 to $40 per ton.—It is understood that the Copper Mountain cyanide mill, which has been closed for months, is to be started up again and kept in steady operation in the treatment of custom ore from the Fluorine and other Copper Mtn. properties; A. H. Head, representing Chicago and Kansas City parties, is in the district and is getting the plant in shape. The mill, which has a capacity of 100 tons per day, was formerly operated by the Sioux Falls Co.—An orebody of good prospecting has been located on the very best and most important of the quartz veins of the district. A complete electric hoisting and compressing plant will be installed and active operations started at once.

IDAHO.

Bannock County.

The new Meadow Creek mill was completed last week and is now treating ore at the rate of 25 tons per day.—The 24-stamp mill at the Jumbo mine is making a test run on ore from Del Rio mine, with a view to leasing the mill to the latter company. The adit at the Del Rio mine is in 900 ft. and has cut an orebody which is 15 ft. wide.

Shoshone County.

(Special Correspondence.)—The building and development of the smaller outlying prospects by forest fires has been the principal feature of the mining industry during the past week. While in no case has the damage been really serious, nevertheless much inconvenience and a considerable number of scares have been caused. During the past week no less than five forest fires have been raging in different parts of the district, and not all of these are under control. A string of lead-silver ore has been made in the property of the Enterprise mine, near Wardner, owned solely by Fred Donaldson. The claims were located about five years ago, and a considerable amount of development has been done. The recent strike was made in a winze sunk from the end of the adit, and at a depth of only about 100 ft. Assays run all the way from $35 to $40 in lead and silver. The Idora Mining Co., paid up at the beginning of the week the mortgage against its property given to Walter J. Nichols of Spokane for the sum of $12,000. The whole of the amount was derived from the sale of treasury stock and was the last payment on the indebtedness of the company, incurred during the financial depression of last year. This is regarded by many as the most promising prospect in the district.—The Federal Mining and Smelting Co. will soon resume work on the Corrigan group of claims, near Wardner, which have been closed down ever since the recent metal depression.—Twelve feet of high-grade shipping ore has been struck in the upper workings of the Surprise Mining Co., at Wardner. Beyond the fact that the strike was quite unlooked-for, no details have yet come to hand. There is said to be of the nature of high-grade ore throughout the district.—A new concentrating table, the invention of Charles B. Walker, of Joplin, Mo., and known as the Coute concentrator, is about to be tested at the Morning mine, at Mullman. The inventor of the table is now in Wallace, and claims that the new apparatus will save 95% of the metal content. Two of the great differences between this table and those usually in use are in the driving device and the riffles. It is driven with a double cam-eccentric, and there are no toggie joints with which to make adjustments. The riffles and deck are made in one solid piece from boiled cypress.—A meeting of the stockholders of the Montana-Standard Mining Co. was held at the beginning of the week, and the old directors were re-elected. A considerable amount of discussion took place with regard to the advisability of erecting a mill at once, but it was ultimately decided to run a 700-ft. drift first. Three ore-shoots have already been exposed in the property, and there are over 1,000 ft. of stopping that can be commenced as soon as a mill is in operation.—The first shipment of ore is about to be made from the property of the Panhandle Mining Co., operating the claim of that name owned by the Pittsburgh Lead Mining Co. This ore will be sent to the smelter at Salt Lake, and will be followed by further shipments at regular intervals. The ore runs about 40% in lead and 30 oz. silver. At the bottom of a 70-ft. shaft 3 ft. of good shipping ore has been found, with about 4 or 5 ft. of concentrating ore. An adit is being run to get under this ore at depth. Wallace, August 15.

NEVADA.

Esmeralda County.

An extension of four months, carrying the tenure to September 1, 1909, has been granted to the Hazel Goldfield Co., which is leasing on the Last Chance claim of the Laguna.—Arrangements have been made by the leading shareholders of the Goldfield Co. to amend the articles of the Company. Extensive work will be carried on by lessees,
on company account, or both. — Block 4 on Combination No. 2 has been leased by the Goldfield Con. Mines, and James H. Skinner, formerly chief geologist of the Goldfield, has been appointed to the superintendency of the property. — The work of installing the new hoisting plant at the collar of the main working shaft of the Grutt Hill Min Co., at Rawhide, is practically completed. As soon as the machinery is in operation the shaft will be lowered another 100 ft., from which point crossings will probably be made. Work has been suspended at the Big Four lease of the Manhattan Con. Min Co., at Rawhide, owing to refusal on the part of the management to establish a semi-monthly pay day, in accordance with the rules of the local miners' union.

LYON COUNTY.

The Mountain View group of mining claims, near Yerington, has been bonded by California capitalists for $100,000, thus depriving the former owners of an option on the Red Crag group for $50,000. — The Nevada-Mammoth Gold Mines Co. will erect a 50-ton mill at its mill-site near the Gig- nox ranch-house. The company is now sinking an incline shaft on its Cambridge vein and at a depth of 50 ft. has found ore which assays over $75 per ton in gold and silver. On another claim there is an incline shaft 550 ft. deep with levels at each 100-ft. point. This and other properties are in shape to attract attention once more to the old Cambridge district. F. H. Meyers is manager of the Nevada-Mammoth and the office of the Company is at Yerington. — A carload of machinery arrived last week at Wabuska for the Kennedy Consolidated in the Buck-skin district. This car included only the hoist and mining machinery, but a mill has been purchased and will probably be running before the first of next year.

NYE COUNTY.

The Huntington mill is being placed at the Bullfrog Pioneer, and the management thinks the 50-ton cyanide plant will be ready for operation the first of next week.

The largest gold brick as yet made at the Keane Wonder was deposited last week with the First National Bank of Elyville by Homer Wilson. It weighed 700 oz. troy, and was worth about $16 per ounce, giving the bullion a value of $11,600. — The old camp of Gold Reef is again attracting attention. A report comes this week of a strike of $300 ore on the Kris Kringle claim, belonging to Dougherty & Fleming. The ore was found at a depth of 350 ft., and carries some free gold. — The Pennsylvania-Tonopah G. M. Co. has purchased a hoist and will at once start sinking on its ground adjoining the Ohio Tonopah Extension.

WHITE PINE COUNTY.

The first shipment of copper from the big plant of the Steptoe Valley Smelting & Mining Co. was made last week and consisted of two carloads of 60 tons each billed to New York City. The Veteran mine is installing a complete fire protection system for its surface buildings, with a storage capacity of 20,000 gal. — James Tucker and associates have started a force of four men at work on a 200-ft. shaft at their Knife & Fork group of lead claims west of Cherry Creek. — Rippetown, a small camp near Ely, was completely destroyed by fire last week. The carelessness of a janitor in lighting a match near a gasoline can was the cause of the fire.

UTAH.

JUNIAR COUNTY.

The directors of the Uncle Sam Mining Co. declared a dividend of 5c. per share, which makes the total amount distributed $25,000. The dividend is payable August 20.

Uncle Sam is the second Tintic mine to resume the payment of dividends, the May Day having made a distribution over two months ago. — It is believed that the old Picnic company, whose claims embrace a part of the Silver City townsite, will resume operations in the near future.

The shaft of the McKinley Mining Co. has reached a depth of 500 ft. and two drifts have been started to fully explore that horizon. — The directors of the Colorado Mining Co. have declared a 10c. dividend. — The ore shipments from the mines of Tintic for the week ending August 14 were 111 carloads. The shipments to the new Tintic smelter during the same period amounted to 18 carloads. It is claimed that the smelter will not be blown in for at least two weeks yet.

SALT LAKE COUNTY.

The management of the Silver Shield mine at Bingham Canyon has recently let a contract for a new 300-ton ore-bin at the Silver Shield mine and has purchased another mine locomotive. — It is believed that the Ohio Copper Co. will soon resume the construction of its concentrating mill at Lark. James MacFarlane has been made managing director of the Company. — The Yampa Smelting Co. last week started its smelter at Bingham canyon. The plant has been completely overhauled and two new reverberatory furnaces and six McDougall roasters added. A new chimney and dust chambers also make the plant more economical in operation.

WASHINGTON.

CHelan County.

The Chelan Butte Gold Mining Co., with a capital stock of $1,000,000, has been organized at Chelan, and a contract has been awarded to E. Cross, of Chelan, to run a cross-cut tunnel 700 ft. which will tap the vein 300 ft. below the point where the ore is being taken out. M. M. Kingman and Al Pershall are at the head of the Company. The properties include the Butte, the Little Butte, Columbia, and the Dakota on Lake Chelan.

Ferry County.

(Special Correspondence). — The lessees of the Republic mine have shipped the third carload of ore to the Granby smelter, at Grand Forks, B. C., and are getting ready for the fourth shipment. — Work has been resumed in the Lac Julie Dreyfus mine, near Danville, with three men, under Theodore Patterson, as manager. This mine has been closed down for from three to four years because of internal strife among the stockholders, brought about by fraudulent issue of stock by the former secretary. Workings to the depth of about 200 ft. resulted in opening an immense body of iron sulphide ore, which assays well in gold and some copper. A shaft, down 125 ft. below the adit level and the bottom workings, were operated with use of a whim. It is a small claim at the Company call to plates installing new machinery. — The Knob Hill M. & M. Co. has shipped a carload of $40 gold-bearing ore to the Granby smelter. A compressor plant has been purchased and will be used in driving a long adit. S. L. Boyer is the manager. — Thomas L. & Wilbur D. Greenough and associates have taken a bond on a group of claims on Huckleberry Mountain, near Laurier, and will incorporate under the name of the Laurier Mining Co. They will start work on an adit, to cross-cut the vein at a depth of 225 ft. Three shifts will be employed. The vein on the property is said to be over 100 ft. wide and traceable for more than 3000 ft. The present workings are three open cuts, a shaft, 50 ft. deep, with a cross-cut from its side. The Spokane Falls & Northern Railway crosses a part of the group of over 1000 ft. from the point where the adit will be started. — The Columbia river is to be opened for transportation between Wenatchee and the mouth of the Sans Poll river, to accommodate the Keller & Indiana S. & D. Co., leaving only six miles of wagon haulage for coke between the Columbia river and the K. & I. smelter. It is estimated that it will require the constant service of a small steamer, now being built, to keep the smelter supplied with fuel. The Company hopes
to begin smelting about September 1. Several small mines in the Keller district are awaiting this for the sale of ore.

—it is reported that the Colville M. & S. Co. will in the near future spend considerable money in its South Half group of claims and smelting plant at Park City. G. Weaver Loper, the manager, has recently returned from New York, where he attended to the financial arrangements.

PHILIPPINE ISLANDS.

(Special Correspondence.)—Benguet’s gold production is steadily increasing and the clean-ups for June show a total of 13,100 pesos, the greatest of any previous month. This is from two mills: the Bua producing 5000 pesos with its six-stamp mill and cyanide plant; and the Benguet Con., or Clarke mine, 7500 pesos. The Clarke output tells a little below normal, owing to the rainy season starting with heavy storms which raised the surface water, flooding the first level below the mill adit. Heretofore all ore has been coming from development work alone, but this necessitated stopping odd remnants of blocks near the surface. The storms also stopped work on the low-level drainage adit, which is now about half way through the lead, showing five feet of $12 ore on the hanging wall. The Bua Co. made a large increase in output, but operated only 24 days, owing to tram line being washed out during first few days of the month. This Company is now being reorganized and six more quadruple-discharge stamps have been ordered by cable so as to double the capacity of the mill. T. C. Kinney, the leading spirit of the Company, is now returning from Hong Kong, having successfully floated a small block of the new stock to pay for the mill enlargement and start more extensive mine development. The mill is now running on Gomoc ore entirely.—The Camote mill was closed down practically all the month. It has been sold to local and Manila parties, who have not yet definitely organized a company, but have closed down the mill to put in a large water wheel and more stamps.

—The Copper King mill, so long closed down on account of shortage of water, is now running to full capacity, but has not yet made a clean-up. All ore is being taken from a vein 50 ft. to the west and parallel to the main Copper King vein.—The latest mining venture to be launched here is the incorporation of the Headwater Mining Co., the stock of which was practically all subscribed in Hong Kong. The Headwaters property is on the headwaters of Antimok river, near the Clarke Adit, and consists of 12 claims or about 250 acres. Another mill is soon to be built by the Major Mining Co., one of the latest companies to enter these fields. Thirty tons of ore averaging $12 to $15 per ton is being broken by Iberos miners, and stored on the dumps ready for milling. Just as soon as there is enough ore on the dumps to pay for a stamp-mill, and in addition furnish it with a year’s supply, a mill will be installed. Water for milling purposes will be obtained from adjacent gulches. Power will be generated by a hydro-electric plant on Gold creek, on one of the lower undeveloped claims. This creek runs 500 miner’s inches of water in the dry season. The Copper King vein crosses four of these claims, which lie east of the Ascension group and about six miles southeast of Baguio. Seven main veins running east and west and dipping south are being developed. Four of these are the Electrician claim and two on the Engineer. Shoots of ore are formed where these intersect the Copper King. Most of the veins carry no silver, and only shows manganese and calcite. The present workings have 800 to 900 ft. of ‘backs’ and all the claims are covered with fine pine timber. The Company is composed of Army officials, and operations are in charge of Mr. Harlbert, the wireless expert and inventor.—Mr. Hanley, an expert representing the United States Smelting, Refining & Mining Co., has been here for the past eight months looking up mining properties, recently returned to the States with an option on the eastern property of Masbate, at a million pesos. He says this country has a bright future before it, and that he will surely return soon. He was unsuccessful in getting options on the larger adjoining producers. Baguio, July 10.

MEXICO.

The Barrancas Mines, Ltd., with mines at La Barrancas, Sonora, will erect a 50-ton concentrating and cyanide mill during the coming winter.—The Sonora Copper Co., Noria, Son., will install a reduction plant. An important strike was recently made on the 700-ft. level of the Cobre Grande mine of this Company.—Lignite coal of good quality has been discovered in Jalisco at Zapotilito, a station on the Zapotlan branch of the Central. An area of 3000 acres is said to be coal-bearing, and during the last five months extensive investigations of the field have been made by the representatives of the house of Garza Galan of Monterey, N. L.—The new mill of the San Rafael mine, at Pachuca, will be completed in a few months. The equipment consists of 40 stamps of 1200 lb. The pulp from the stamps is to be re-ground, after classification, in three Krupp tube mills, and thence fed through settlers to Brown air-agitation tanks for cyaniding. The battery fluid will be cyanide solution, which will be increased in strength in the Brown tanks. Space has been left for concentrators, but tests indicate that this treatment step will not be needed, as a good extraction is obtained in short time with air-agitation. From the Brown tanks the pulp will be conveyed to two separate units of Moore filter cloth. From these filters the slime and fine sand will be thoroughly wasted, the pulp will be discharged to the dump. E. Girault is the manager.—The Guana-cev Tunnel Co., Guanacev, Dgo., is planning to install a large power and machinery plant, with air-compressor, soon.
Special Correspondence.

LONDON.

Retirement of Prof. Gowland from Royal School of Mines. — Litigation over Flotation Processes.

In some of the London papers several references have recently been made to the approaching retirement of Prof. William Gowland from the chair of metallurgy at the Royal School of Mines. The actual reasons for the retirement have not been given, and, instead, a considerable amount of mystery has been mustered up in connection with it. The fact is that the appointment, being a Government one, is subject to the age limit, that is to say, to the "too-old-at-sixty" theory. In certain departments all appointments become automatically void when the age of sixty is reached. In some cases an extension of time is given, and the limit made sixty-five instead of sixty. This rule is all very well in its way, but occasionally it becomes ridiculous when public men in the height of their usefulness are mechan-ically dethroned. Examples of this are to be found in the cases of Prof. Ray Lankester, who had to quit the directorship of the Natural History Museum, and of Sir Caspar Purdon Clarke, who, when the South Kensington Museum no longer wanted him on account of his age, was promptly snapped up as a treasure by the New York Art Museum. Now it is Prof. Gowland who has had to obey this automatic rule. I believe that the Board of Education would have given him an extension of time, but for the fact that the School is approaching its reconstruction under the Imperial College of Technology. It was felt that it would be best to allow the new professor to be responsible for the re-organization of his department, instead of the professor who would have to retire before long in any case. Thus it comes that "our dear professor," as he is properly called, will terminate his duties at the end of the session in June 1899. Before long we shall see the public announcement inviting applications for the post. The duties will have to be taken up in April, and the new professor must make up his mind to spend the latter part of his life teaching, for it is almost certain that he will not have to be British subjects, School of Mines or college men, and must have gained experience by having been directors of metallurgical operations.

As is pretty well known by those interested in ore-concentration by the flotation processes, there is litigation going on between the owners of the Elmore patents and the holders of the Sulman-Picard-Ballot patents. To give a complete account of all the details of this litigation would occupy too much space, and few would care to read the full details. The first flotation patent was taken out by Frank Elmore in 1898. This covered the old oil concentration-process. There were earlier patents taken out in England and the United States for separating metals and sulphides from gangue by means of oil, and in fact the selective action of oil on metallic-surfaced particles has been known from time immemorial. In these earlier patents the ore was kneaded in the form of a paste and water was used for washing out the gangue. Frank Elmore was the first to use water and oil in bulk and make with the ore what may be called a freely flowing pulp. This is what the Elmore companies claim as the master patent of all flotation processes, but I am quite sure it would occupy too much space to rewrite that question of patents. In any case, it may be caused by the introduction of improved ideas.

I have not mentioned the Delprat & Potter processes which use acid without oil, for these do not come within the scope of the present litigation. One of these days when we know more about the theory of flotation processes, we may find that it is the accidental presence of oil in the acid waters of these two processes that gives rise to no small part of their efficiency. The processes are operated at high temperature, and the water from the condensers of the steam engines are used. I should not be at all surprised if eventually it be found that the lubricating oil of the engines plays an important part in the flotation vat.

TORONTO, CANADA.

The continuance of heavy ore and concentrate shipments from Cobalt has at last begun to have its effect upon the stock market, which after having been extremely dull during some weeks, is again active, with a strong upward tendency as regards the principal producing mines, Nipissing and La Rose being the leaders. The July shipments broke all records, with a total of 2584 tons, being 60%
above those of June last and 58% more than the figures for June, 1907, the banner mid-summer month of that year. The total shipments for the first seven months of the present year are approximately 17,782 tons, as compared with 7,796 for the corresponding period of 1907. The shipping mines for July were as follows:

Mine. Pounds.

La Rose 1,029,800
Nipissing 725,547
O’Brien 725,547
McKinlay-Darragh 465,360
Trelawny 401,710
Silver Queen 255,000
Nancy Helen 227,007
Right of Way 258,530
City of Cobalt 212,730
Drummond 172,020
Watts 147,610
Fort Lake 95,228
Conigan 82,290
Buffalo 63,560
Silver Leaf 61,410
Kerr Lake 60,674
Hudson Bay 60,000
Townsire 45,600
Crown Reserve 44,000
Penson Lake 41,227
Nova Scotia 40,230
Cobalt Central 37,440
Temiskaming 40,000

Total 5,165,200

Some of the largest shippers are likely to considerably increase their outputs. With this view the Temiskaming is sinking a three-compartment shaft, to facilitate the handling of the ore. At the Trelawny a rock-crusher has been installed and more machinery is being put in, which is expected to double the yield, in addition to enabling the company to ship a better grade of ore. The University mine, formerly a heavy shipper, operations on which were discontinued for some time before the merger with the La Rose, will soon be producing on a large scale. A force of men is now busy on preliminary work. A statement of the production and earnings of the La Rose for the two months of June and July gives a total output of 745 tons, carrying 501,286 oz. silver, valued at $210,196. Several important discoveries have recently been made. The Crown Reserve has sunk two shafts, to be the main big veins, to a depth of 20 ft. The width at this point has not been ascertained, but it is apparently equal to that in the open cut 190 ft. to the west, which shows 36 in. and has yielded much rich ore. Two nuggets of about 100 lb. each have been extracted from the crosscut. At the La Rose a strike has been made in the North adit, 140 ft. from the face of the cliff. It is stated that high-grade ore 3 ft. wide was found. This is regarded as significant, as it is the farthest point north at which work has been done on the property. Other rich discoveries have been made on the Right of Way, and on a leasehold worked by the Cobalt Central.

Development in James and Smyth townships on the Montreal river is proceeding but slowly, and though numerous discoveries have undoubtedly been made, the expectations of those who hoped to see a large camp spring up, possibly rivalling Cobalt, have thus far been unrealised. This is largely attributable to the fact that these properties are in the hands of prospectors who have not the means to develop them, and cannot in the present state of the money market produce funds, and will not sell to those who would be willing to operate them, except at prices which are regarded as exorbitant.

The directors of the Crown’s Nest Pass Coal Co. at a meeting held in Toronto on August 7, authorized President George G. S. Lindsey, now at Fernie, B.C., to proceed at once with the re-construction of the portions of the Company’s plant which had been destroyed by fire. It was estimated that the net cost would be in the neighborhood of $50,000. The fire destroyed the hospital, and did much damage to the coke-oven plant and other equipment, the total loss to the Company being placed at about $200,000, covered by insurance to the extent of $150,000. The work of rebuilding will be started immediately. Coal mining has been resumed, and it is expected that the normal output will be reached within a week.

The Ontario Government has called for tenders for three mining leases in Cobalt town, including the Nation grounds and adjoining rights-of-way, and four townsite lots, with rights under adjoining streets. The tenders will be opened September 16. The leases will be subject to a 25% royalty on the gross value of the output.

ROSSLAND, BRITISH COLUMBIA.

Centre Star Earnings. — Low Costs at Granby. — Improved Plant for Dominion Copper Co. — Shortage of Coke Following Fire at Fernie.—Sloan District.

The year 1908 has so far been a profitable season for the Rossland mines and, as the outlook for copper is bright, better earnings are anticipated for the remainder of the year. The Centre Star group of the Consolidated Mining and Smelting Co. of Canada is estimated to be making a net profit of approximately $40,000 per month on its operations; the Le Roi Mining Co. is not shipping as heavily as, and, of course, is not making as much money, and while the Le Roi No. 2, Ltd., is shipping only about 2,000 tons of ore per month, a higher grade product is going to the smelter than from either of the two first mentioned mines, and the fact that this company has already paid four shillings in dividends this year is evidence that it is earning a profit.

Seven of the smaller mines now under lease have made small shipments of rich ore, but the quantity of ore they have sent to the smelters has not been as great as was expected earlier in the year. The leases of the Evening Star and Blue Bird mines have tared well, and have made money on the venture, but the other properties have little more than paid expenses. The Granby mines are producing steadily about 22,000 tons of ore per week, and are making copper at the Grand Forks smelter for $18.50 per lb. The B. C. Copper Co. is mining and smelting 13,500 tons of copper-gold ore per week and is making copper and landing it in the East for $21 per lb. The Dominion Copper Co. is running only the big furnace at the Boundary Falls smelter, and is treating about 650 tons of ore per day. The Company’s large smelting furnace (installed by the City of Brooklyn, Rawhide, and Sunset mines at the rate of 4000 tons per week, and is bringing in 2000 tons of ore, high in iron, from the Athelstan and Mountain Rose mines for fluxing purposes. The Dominion Copper Co. is installing important improvements for handling ore economically at the mines, and at its two small furnaces, and until these facilities are installed they will not get their cost of making copper down to the low point now reached by many operators. A large new body of ore has been disclosed in the Brooklyn mine, carrying $4.50 in gold, 50c. in silver, and 2.25% copper. Shipments are now being made from this mine.

Just at this time when the Consolidated Co. was going to re-open the Snowshoe, and the district is looking more prosperous than ever, the rains in the past, a calamity in the Crow’s Nest Pass coal country threatens to cut off the Boundary coal supply. A devastating forest fire has destroyed the town of Fernie and crippled the coke-making industry of that district. Of late the several hundred tons of coal consumed daily in the Boundary furnaces has come entirely from the Crow’s Nest ovens. The Granby Co. is making extensive repairs to its smelting apparatus, and now has several furnaces out of commission so that emergency supply of coke will no doubt carry this concern over several weeks. The B. C. Copper Co. also has about three weeks’ supply of coke on hand; but the Dominion Copper Co. has only about a week’s supply of this commodity in its bins. It is anticipated, however, that the
coal company will get new slack-hams and trestles to the coke-ovens erected within the next ten days, and that coke-shipments to the smelters will be resumed in a couple of weeks. If there is a much greater delay than this it is likely that the Consolidated smelter at Trail, and the Le Roi smelter at Northport, will have to shut down.

The Vancouver group of mines, which the Le Roi No. 2, Ltd., has had under bond, situated in the Slocan district, has been taken over by a London development company known as the Van-Roi Mining Co. The capital of the company is £31,500, divided into 30,000 preferred shares of £1 each, and 60,000 shares, common, of 1s. each. The stock issue has all been subscribed. The Vancouver group has a promising future before it.

MEXICO.

The Chamber of Mines of Mexico, through its president, José Luis Riquena, has issued a circular asking for bona fide expressions of opinion by persons of prominence here and abroad upon the proposed new articles in revision of the mining law, and for information regarding “negotiations for the purchase of mines or for the organization of foreign companies for that purpose that have been suspended through fear that such a bill will be passed.”

Since the starting up of the Greene-Cananea Copper Co.'s smelter last month good news of important work seems to be pouring in, not only from Cananea, but also from all parts of the State of Sonora. One of the most important new departures is the bringing of fuel-oil to Cananea for the Greene-Cananea company from Texas and Oklahoma. L. D. Blissett, president and manager of the Greene-Cananea, has contracted for 1,000,000 bbl., to be delivered in two and one-half years, at the rate of 150 to 200 cars per month. Under the concession from the Mexican Government this comes in free of duty, and will admit of a great saving in the operation of the Cananea plant. At Nacoza the Mocotzuma Co. is increasing its production. Twelve months west from Nacoza, the Dawson Gold Mining & Milling Co. has bought the Creston de Oro mines, and has installed a 30-stamp mill with plates and concentrators. At Magdalena the Black Mountain Mining Co. has installed the new machinery for its electric power plant, and it may be expected that that company's production will soon be materially increased. The Cerrro Colorado Mining Co., operating in the Altar district, 60 miles west of Magdalena, where it has some 145 acres, or practically a whole mountain, of quartz-porphyry running about $5 per ton, and for which records show, numerous sums have been taken from the richest pockets, is planning an enlargement of plant to handle more economically its immense bodies of low-grade ore. The Industrial Mining Co., at Carbo, Sonora, is developing a good body of lead ore, and the Douglas Copper Co., now operating its smelting plant at Funcion has already become an important institution to the producers in that part of the State. At the Frontal mine, operated by M. Mexico & Orient Railway, has taken over the concession of the late J. F. O’Gorman for 15,000 hp. on the Fuerte river at kilometre 184, east from the port of Topolobampo, and will establish a hydro-electric power-plant at that point with the idea of providing electric power for consumers along the line of the railway through to Choix, and possibly as far east as Urique in western Chihuahua.

In the camp of El Oro, State of Mexico, the four principal producers continue to have a combined production of $1,500,000 monthly, of which $170,000 is net profit. Of these four, one is the Esperanza Mining Co., controlled by John H. Kirby, the latest plan being to take up additional ground of Mr. Kirby's, re-organize under the name of La Reina y Anexas, with $200,000 capital, of which one-half shall go to Mr. Kirby for his interest, and half to the company for the capital for development purposes, with preference shown to the stockholders of the old Chihuahua Mining Co., who will receive also from Mr. Kirby a bonus of 10% of their purchases. The English companies are making large efforts to reorganize; that of Mr. Robert Brannock, the Victoria Plc., is to take over the old Consolidated Mine Co., with more than $500,000 in equipment and machinery. The Victoria will continue its own development work. The recent work of the Dos Estrellas on the Victoria gives great promise for the latter.

JOPLIN, MISSOURI.

Organization of Zinc Ore Tariff Club. — Importations of Zinc-Ore from Mexico. — Ruling as to Meaning of 'Calamine' — Limiting Missouri Zinc Output.

During the past month a movement has crystallized to exert every effort to place a tariff upon zinc ores imported into this country. This movement has been started in Joplin by the calling of a meeting of the leading zinc producers, who promptly organized a working body called the Zinc Ore Tariff Club for the purpose of amalgamating the different interests in the district into a harmonious whole whose sole object would be to secure the passage of a tariff act for the protection of American zinc producers. The club is organized upon a non-partisan basis, and the present object is to educate the people of the zinc-producing camps as to the peril from outside competition.
and then presenting the matter with strong endorsement before the ways and means committee of Congress, which will speed the course for the purpose of revising the tariff schedules.

The organization consists of a central body of which there is a president, vice president, and secretary, and a board of directors. The first three offices are elective by the whole district. The directors consist of five men appointed by the president, and the chairman of each of the local clubs in the different camps of the entire district. There were appointed at first five directors, and these, with the president and secretary, constituted a committee which had in charge the formation of other clubs in the other camps of the district. So far there have been organized, in addition to the central body, a club at Joplin, Webb City, and Carterville.

The club is vigorously spreading knowledge as to the importation of zinc ores. It appears that since 1905 the importation of zinc ores from both Mexico and British Columbia has increased heavily, until some of the smelters boast of using no ore whatever from Joplin. In 1905, when the first important shipments were made from Mexico, the total tonnage was but 30,000, consisting chiefly of silicates and carbonates, zinc-blende being almost a negligible quantity. In 1906, 50,000 tons of ore was shipped into this country, and in 1907 importations reached 150,000 tons. In 1908 the shipments have not been so heavy.

owing to the low price of the metal, the minimum price for which is 5c. in settlements for Mexican ore. Below 5c. the Mexican operator has to cease operations. However, many of the smelters continued to settle for Mexican ores on the basis of spelter being 5c. at St. Louis, although it has been below 4½c. This has brought into the country about 1000 tons of zinc-ore per week. These imported ores make as good spelter as Joplin ores for certain purposes, although for sheet-zinc they would not be such strong competitors. The ores run from 27 to 40%, and, being calamine and carbonates, they require no roasting previous to distillation in the furnaces. This renders them profitable for smelting, and the menace to Joplin ores has grown into goodly proportions. The total ore production for 1907 in the Joplin district was only 280,000 tons, running perhaps on an average 50% zinc. The Mexican importations averaged only 35%, but even then the importations were more than sufficient to account for the surplus stocks of spelter which the spelter-dealers had on hand at the first of the year.

With this menace staring them in the face the operators have been strenuously fighting to get the treasury department to levy a 20% ad valorem duty on zinc-ores under the paragraph of the Dingley law which provides such duty upon “metallic mineral substances.” In this way the operators would secure a benefit of about $4 per ton on all the blendez and carbonates. Calamine, however, is specifically placed upon the free list. The Treasury Department granted their request, and litigation has been in progress for over two years. Before the New York Board of Appraisers the importers were successful in defeating the movement, and the case was carried into the District Court, where there was handed down an opinion which also sustained the importers. The case has been appealed to the Supreme Court, and is still pending. The importers contend that calamine is not a metallic mineral and hence duty-free, and that blends should not be classified as “metallic mineral substance.” The Joplin producers contend that carbonates of zinc are not calamine, but that calamine is strictly a silicate ore; and that undoubtedly blende is a “metallic mineral substance in a crude state,” and therefore subject to a duty, under the present schedule of 20%. This case will be vigorously prosecuted while the efforts of the new Zinc Ore Tariff Club will be devoted to securing legislation which will be so specific in its terms as to completely shut out all zinc ores. The club will advocate a tariff upon zinc-ore equal to the present tariff upon lead ore based upon the metallic content. Lead pays a duty of 1½c. per pound on the metal-content. Spelter is also dutiable at the rate of 1½c. per pound.

The importance of this movement cannot be over-emphasized. The question is of non-partisan character and in the plans made for a wide range of activity. Branches of the club will be established in every zinc-producing camp of Missouri, Kansas, Oklahoma, Arkansas, Wisconsin, and Illinois. Anyone having any interest in the zinc industry—and in the Joplin district that includes everybody—is eligible to membership. Chas. T. Orr, of Webb City, is president, and C. B. Guinn, of Webb City, is secretary. With the present low prices paid for zinc-ores in this district and the consequent period of distress there is little need to say that the movement is rapidly gaining favor and strength.

A large number of mills have closed down again to await a better price for ore, thus reducing the rapidly accumulating surplus. It is estimated that this amounts to as much as two weeks’ production under normal conditions. The past fortnight, however, has noted larger shipments at an increased price, the basis being $36 for 60% ore. This has reduced the surplus about 4000 tons, but the tendency to re-open mills when the price of zinc-ores advances quickly depresses any advance almost as soon as made.

**Part of Butte, Montana.**

**New Plant at Colonel Sellers Mine.—Butte-Bajstikova Co.—Development on East-Side.—East Butte Mining Co.’s Progress.—Position of La France Copper Co.—Pumping Plant installed by Boston & Montana Company.**

The new hoisting machinery has been installed on the Colonel Sellers claim by the Butte & New York Copper Co. and the shaft is being unwatered preparatory to a resumption of sinking. A 250-gal. electric pump has been purchased and will be installed at the 700-ft. station for the purpose of exploring the veins at that depth, though it is not expected that commercial ore will be found there. The new engine has a capacity to work to a depth of 2000 ft. The work is in charge of John Billes, an experienced
of every person who was interested as an original subscriber, and a rather remarkable thing when compared with a score of other mining ventures in which Butte people lost millions. Mr. Sullivan not only "made good" in the first place, but after the financial panic, when it became inadvisable to try to raise funds by the sale of treasury stock, and when other concerns became bankrupt, he succeeded in re-financing the company, and the East Butte passed to some of the strongest copper interests in America.

The La France Copper & Mining Co., which owns the Lexington mine at Butte, and experimenting with a new size process, operated at a loss during the year ending June 1, according to its statement to the authorities. The proceeding year it reported net earnings of $491,000, upon which it was taxed $4266. This has not been paid, and the property of the Company has been sold for delinquent taxes. The mine, which became the purchaser, in the absence of other bidders. When the Company redeems the property it will have to pay a 10% penalty and 12% interest on the unpaid tax. The fact that the Company is willing to be assessed so high an interest would indicate its financial difficulties. It also found itself unable to pay interest on its coupon bonds, due in January and July last. The United Copper Co. has filed its own petition, but has used its money, and the bondholders have accepted the proposition. The Company owns a reduction plant at Basin, Mont., and is trying to sell it. Much hope is placed on the new orebody opened above the 800-ft. level of the Lexington, which is developing encouragingly. Samples of the ore have assayed as high as 6% copper, and 6.2 oz. silver. The ore is quite free from zinc, and contains a great deal of gold. The company bought the mine at a very low price, as it was developed and mined above the 500-ft. level, but which the engineers could not find below. During the year ending May 1 the Company spent $301,501 on the zinc-mill. Operations were stopped when the citizens of Walkerville brought an injunction suit on account of the great dust created by the mill. The Company appeared willing to close the mill, but for it did not answer the suit and allowed it to go by default.

John A. Ryan, superintendent of the North Butte Extension Co., has returned from New York, where he had been assisting in the re-adjustment of the financial difficulties of the Company. He was called to Butte before matters were settled in New York, but he says there is no doubt that everything will be adjusted satisfactorily in a short time, and work on the property will soon go on again. The company has paid to the men who have put their money into the Company full confidence in it, and believe that the Extension will have all the possibilities of a big copper producer. They will therefore provide funds for paying off the Company's debts, and resume development work.

The Boston & Montana Co. is installing two new Nord-berg quintuplex pumps on the 1200-ft. level of the Leonard mine. They will have a capacity to raise 600 gal. of water per minute from the 1200-ft. level to the surface. The Company will install two more in the near future. The necessity for additional pumping facilities is caused by the extension of the drifts and cross-cuts, thus increasing the water-flow, and by the suspension of work by the Reins Co. for several years. The water is drained off from this direction. The Reins shaft is filled with water from the 500 to the 1200-ft. level. The Boston & Montana has resumed sinking on the Badger State, and there seems to be little doubt that that property will be developed into a producing mine, as it joins on the east side of the Jesse mine of the North Butte Co., the Jesse vein being traced through the Badger State. The shaft was sunk last year to a depth of 560 ft., but all work was stopped at the time of the general suspension. It has not been decided how deep the shaft is to be sunk, but stations will be cut every 200 ft., and when sinking ceased cross-cutting will be done from the station. At present the Boston & Montana is carrying its mining to the East and West Cohnus and Leonard mines. The geologic conditions in those mines have greatly improved, and the trouble reduced to the minimum. A good portion of the old stopes are still bulkheaded.
Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Glycerine is an ideal lubricant for the stuffing-boxes of gasoline pumps, as gasoline will neither mix with nor dissolve it.

Ozocerite is a natural paraffin, and is used for making shoe and leather polish, sealing wax, candles, and in the insulation of wires.

Oil spots on marble slabs can be removed by applying a paste made of 1 oz. potash and ½ lb. whiting. The paste should be left on the marble about five hours.

Amalgamation plates may be dressed with a 1.6% solution of hydrochloric acid if it is desirable not to use cyanide. If the commercial hydrochloric acid is used, the proportion should be 1 to 20.

Soldering flux which will cause no oxidation may be made by reducing lead and tin to an impalpable powder and then mixing these with chloride of zinc. This compound is made into a paste by the addition of vaseline or glycerine.

Washed metal is cast-iron from which most of the silicon and phosphorus have been removed by the Bell-Krupp process, without removing much of the carbon, so that it still contains enough carbon to be classed as cast-iron.

Navigable streams are those which have been so declared by the Federal Government. The physical characteristics of the stream have no essential bearing upon its present navigability, except in so far as they influence the official decision.

Theodolite is the English name for an engineer's transit. The instruments are fundamentally the same except that the telescope of the former is made longer, securing thereby better definition, but hence cannot be reversed on its horizontal axis.

Cupellation losses are due to absorption and volatilization. The loss of gold and silver depends upon the temperature of cupellation, the amount of lead with which the gold and silver is cupelled, the physical condition of the cupel, and the nature and amount of the impurities present.

The 'four plumb-bob' method of transferring a meridian into a mine is advantageous in some cases, since it requires no trigonometrical calculations. In particularly favorable circumstances the shaft may be plumbed without interrupting hoisting operations, since the plumb-bobs are hung close to the walls of the shaft. It is particularly adapted for use in a multi-compartment shaft. Four plumb-bob strings are so hung in the shaft that the lines joining each pair intersect beyond the lines of the shaft. The azimuth of each line is accurately determined above ground, and the distance between the strings is measured, for use as a check underground. In the underground work it is necessary to 'range in' an engineer's transit until it is exactly at the intersection of the two lines, and hence any desired azimuth may be determined directly by instrumental settings.

Steam-fitters' cement, made of red or white lead mixed with linseed oil, to which rubber or gutta-percha has been added, is much better than common paint. The rubber or gutta-percha should be dissolved in sufficient carbon disulphide to give it the consistence of molasses, then mixed with the oil and left exposed to the air for about 24 hr. before the red lead is added. If oxide of iron be substituted for the red lead the cement will be less brittle.

Black prints, having a white background and black lines, may be made from ordinary tracings by a number of processes. The best method is to make a print in the usual way, with a special black and white paper, and then to use this negative to make either black and white, or blue and white, prints. One of the best of these specially prepared papers is called Vandyke, and is manipulated the same as line-print paper, except that it requires a bath in a fixing solution after the usual water-bath.

Sand-lime brick is manufactured from sand and lime, the latter being thoroughly hydrated or slaked before using. After the sand and lime-hydrate have been mixed the mixture is molded-in presses. The brick is then loaded upon steel cars and run into a horizontal steel cylinder, subjected to a steam pressure of 125 lb. per square inch for about 6 to 10 hours. The lime and silica combine while under pressure in the steam bath, and form calcium silicate, which is practically insoluble at ordinary temperatures, and which binds the sand grains firmly and durably.

Neutralization of potassium cyanide in waste waters from cyanide plants may be accomplished by the use of sulphuric acid. The waste waters seldom contain more than 0.02% KCy, hence the quantity of sulphuric acid theoretically required would be only about 1/10 lb. per ton of solution. The difficulty is to effect uniformity of mixture of so minute a quantity of acid with so large a volume of solution in a brief period of time. Wicking extending from a vessel containing the acid and dipping into the launder through which the solution is being discharged, gives a fair degree of success. The best protection against damage to stock is perhaps to be found in plenty of barbed-wire, rather than in neutralization of the cyanide. Horses, dogs, and most domestic animals avoid waters containing cyanide, but the cow seems wanting in discrimination. The dose that proves fatal depends less upon the degree of concentration than upon the absolute quantity taken. It is doubtful whether a cow could drink enough of 0.01% KCy solution to get a fatal toxic effect. Very weak solutions concentrate by evaporation in ponds, so that storage reservoirs may thus become dangerous.
Diffusion as a Factor in Ore Deposition.

The Editor:

Sir—H. H. Knox, in your issue of August 1, affirms that there is no parallel between the case cited by me of the cooling of a slag in a slag-pot and that of the cooling of a fused rock-mass, so far as the operation of Soret's principle is concerned, because of the difference in the time element presented by the two cases. Therefore, I think, to bring the time element into this discussion, because in the first place, as Mr. Knox implies he is aware, the case of the fused rock-mass was discussed as a maximum, and therefore beyond the influence of time, and the numbers in the case of the slag show that these are sufficiently within the range of the maximum to render their discussion as being still under the important influence of the time element of no practical value. But Mr. Knox has further made an interesting suggestion of a possible cumulative concentration of a dissolved metal into an orebody by its diffusion through a small residuum of fused magma after a large portion of the original fused whole has become successively crystallized into minerals that have solidified without entraining within the body of their crystals any of the dissolved metal, the whole of which is therefore concentrated in the still fused residuum. Unless the crystals, as they form, separate by gravity from this residuum there will be no more effective segregation of the metal into the colder portions of the rock-mass than when the whole was fused. The residuum, with the metal content, would be uniformly spread throughout the rock-mass now only semi-fused, and, as regards the fused portion, subject to the same temperature-difference as before. There would have been no concentration regarding the mass as a whole by reason of this partial crystallization of the rock-mass. If the temperature-difference of the hottest part (say the centre), and the coldest part (say the periphery), was as we may conceive it to have been, namely, the difference between say 1500° and 3000° absolute, and if this ratio were not disturbed, then there would be still half as much of the metal as a percentage in the extreme centre as there would be in the extreme periphery and every gradation between, and just the same relative proportions as in the ease of the original rock-mass, when, instead of being partly crystallized it had been wholly fused. The mere crystallization of certain minerals has not affected the metal-content of any part, other than as between a crystal and the surrounding fused magma, and there is thereby no further practical concentration.

If, however, we imagine the extreme ease of the complete separation by gravitation of the first-forming crystals from the residuum of fused magma (and I do not think we have much justification in nature for assuming this extreme case), the dissolved metal-content will then be concentrated into this fused residuum, still only varying in degree of concentration within itself between the same temperature limits as before. In the coldest portion of the residuum there will be a certain percentage of the metal, and this will diminish imperceptibly toward the hottest portion, where it could hardly be less than one-half of the percentage to be found in the coldest portion. There has so far been no more segregation by Soret's principle than in the original rock-mass as a result of partial crystallization. The Soret principle has been used to explain a class of orebody where there is a sharp break, so to speak, in values between the orebody and the adjacent country from which it is supposed to have magmatically segregated. To have been segregated by Soret's principle there would be no practical definition between the periphery or first-cooling, or the centre or last-cooling portion of the rock-mass. If the periphery contained any commercial percentage, the centre would be so near in grade to the periphery as to be a commercial, or potentially commercial, orebody also. Moreover, there is no evidence that fused rock-magma could dissolve so large a quantity as several units per hundred of a metal as would be implied by a commercial orebody, and it must be remembered that the Soret principle can only be used to discuss the movement of dissolved substances. The influence, therefore, of movement by Soret's principle of the metal within the residuum of the rock-mass left fused, is no different from that obtaining where the whole rock-mass was in the fused state. There will be no sharp separation of the residuum into a smaller portion containing a large percentage of the metal, and a portion immediately adjacent containing it in inappreciable amounts; on the contrary, there must be a gradual transition from a certain percentage to something not very much less. The ratio of the highest to the lowest metal-content of any such residuum as we have discussed would be the same as in the original wholly fused mass. Would this ratio be sufficiently large to make a distinction between an orebody on the one hand and country rock on the other out of the same original fused rock-mass? I think not.

It seems to me fatal to apply this principle to cases where the ratio of the metal-content of the portion called the orebody differs so much from the adjacent rock, assumed to be the original source of such metal, as to make this distinction between an orebody and country rock possible. If we found an orebody containing, say 5% of a metal on the periphery of a rock-mass, we would find in the centre something like 3% and every grade between these limits regularly disposed between periphery and centre. If the periphery were an orebody, so would be the centre. The Sudbury ore deposits display no gradual increase of metallic content from periphery to centre, and yet they are used as an illustration of the action of Soret's principle. I think this is because the limits of the principle have not been fully recognized by those who have sought to make use of it. Furthermore, referring to facts of observation, it is noteworthy that the Sudbury ore-deposits are not even approximately continuous around the
The periphery of the intruded norite, but are distinctly localized into masses of limited extent laterally and vertically.

San Francisco, August 5.

Geology of the Lucky Boy Mine, Nevada.

The Editor:

Sir,—In extension of the editorial remarks in your issue of July 11, I beg to submit further details concerning the Lucky Boy and Mountain King properties, recently purchased by the Chicago Exploration Co. These are in Esmeralda county, Nevadn., seven miles southwest of the old town of Hawthorne. The claims, seven in number, are situated on the eastern crest of the mountain range which rises abruptly from the level valley west of the town. The range is quite steep, and is cut by many narrow and precipitous gulches. The old stage road from Hawthorne to Bodie crosses the property several times as it winds and curves around the hills in its ascent to the summit. The mine is 2200 ft. above the floor of the valley. The rock formation at the mine is hornblende-granite intrusive into limestone. The limestone has been very much deformed and distorted by the intrusion; very acute folds and bends being frequently observed. This deformation has been so severe that the original stratification of the limestone is practically destroyed, and almost any variation of strike and dip can be found. The most persistent strike, and one which may be taken as an average, is N.60°E., and the dip varies from 60° from the horizontal to almost vertical, pitching toward the south. The granite occurs massive and also in dikes through the limestone; these dikes vary from an inch or two up to 50 ft. wide, and are roughly parallel to the bedding-planes of the limestone. Irregular masses of granite are distributed throughout the limestone, and both dikes and masses are connected by an intricate network of small granite stringers which cut through the limestone in a multiplicity of directions. The limestone has been altered to a fine-grained gray marble, and in a few places coarse crystalline calcite is seen. Along the contacts white mica, mien-schist, and bunches of lime-feldspar are sometimes seen, but in most cases the line of demarcation between the limestone and the granite is perfectly sharp, well-defined, and the absence of contact-minerals is particularly noticeable. Both rocks have undergone considerable fracturing and fissuring.

In the smaller dikes the granite is uniformly fine-grained, but in the larger ones, and in the massive granite, the texture varies from very fine at the contacts to quite coarse in the body of the granite. A fresh specimen of the granite showed it to consist of quartz, orthoclase, and considerable hornblende. A few large and scattered biotite crystals also occur. Running through the granite are several basic dikes containing a small amount of quartz, relatively more feldspar, and from 50 to 75% hornblende. The texture of these dikes varies from a very fine homogeneous gray rock to a very coarse-grained one in which the individual hornblende crystals are often a couple of inches long. The principal geologic feature is a well-marked fault which is subsequent to the intrusion of the granite, and cuts impartially across both formations. This fault strikes N.72°E., and dips 70° to the south. The orebodies are found on this fault, and in the mining operations it is shown as a persistent seam of gouge. The ore is principally argentiferous galena, and an intricate mixture of silver sulphides or 'black metal'. The gauze-minerals are quartz and impure calcite, the quartz predominating. Silver chlorkle and bronzile also occur, lining small fractures and fissures, and their bright blue and green colors are very conspicuous.

The orebodies follow the fault-fissure and vary from a few inches to 3 and 4 ft. in width. The ore is not continuous along the fault, but pinches and disappears completely at times, leaving only the seam of gouge as a guide to further mining. 'Feeders' or small stringers of ore in cross-fractures come in, generally from the foot-wall, but occasionally from the hanging-wall side, and apparently have had an important influence on the deposition of the ores. It is at the junction of these feeders with the main fault that the larger orebodies occur. These feeders, and not the nature of the wall-rocks, have apparently determined the arrangement of the ore-shoots, for although in most of the mine-workings both walls are granite, the ore occurs impartially in either formation and is seemingly independent of the walls. The mine is opened by two adits, through which most of the work is carried on, and also by several shafts and winzes. About 1500 ft. of work has been done, and from the showing so far made the mine gives promise of a productive future. Regular shipments of a good grade of ore are now being made. The ore is sacked at the mine and hauled by teams to Thorne, whence it goes to the smelters by rail.

Goldfield, Nevada, August 5.

Methods of Copper Assay.

The Editor:

Sir,—In your issue of July 18, M. L. Requa in an article on the 'Experimental Mill of the Nevada Consolidated Copper Co.', makes mention that analyses of low-grade copper ore made on the ground by the iodide and cyanide methods gave results about 0.12% higher by the iodide method; while certain samples of concentrate assayed electrolytically by the Tennessee Copper Co. gave results from 0.61% to 2% higher than the cyanide results obtained at the mill. From an experience covering numerous comparisons of the three methods, I beg to express a few opinions concerning the accuracy of these methods and to give some results obtained by me in ordinary routine work, taken at random from the records of the King Metallurgical Laboratories.

In the cyanide and iodide assays the usual method is to precipitate the copper on aluminum foil from a sulphuric acid solution. As ordinarily performed the separation is not complete, due to the incomplete expulsion of the nitric acid by the sulphuric acid, or to the presence of large amounts of iron salts. The final traces of copper may be brought down by the
addition of hydrogen-sulphide water, followed by washing with the latter. Washing with water or undue exposure of the copper, whether in the finely divided metallic form or as the sulphide, causes an oxidation of the latter, followed by its solution and loss. Consequently the precipitate should be kept under hydrogen-sulphide water as much as possible during the washing. Provided the ore is of such a nature that the copper may be accurately precipitated electrolytically from a simple solution, the results by the iodide or cyanide assay, where the treatment with hydrogen sulphide is omitted, will usually be lower. Furthermore, there is always a loss in filtering a copper solution. Often several hundredths of one per cent of copper will, regardless of the number of washings, be retained by the filter-paper.

On the other hand the potassium iodide used in the iodide assay is very easily reduced. Even traces of certain impurities in the precipitated copper or in the reagents used will liberate an appreciable amount of iodine, and cause high results. This will easily account for the difference of 0.12% between the iodide and cyanide assays mentioned by Mr. Requa. In a carefully conducted iodide-assay, in which hydrogen-sulphide water has been used, the gain in copper due to impurities need not exceed the loss in handling. Close checking of duplicates is a guarantee of the accuracy of the work, provided the standardization has been correct, but any carelessness in handling causes a gain or loss in the amount of iodine liberated. The same is not true of the cyanide assay, where the titration is rougher, and much is left to the judgment of the analyst. Of the two methods, the cyanide, while satisfactory for ordinary work, is less preferable to the iodide. Furthermore the cyanide method depends for accuracy upon the same working-conditions as to bulk, foreign salts, and free ammonia as prevailed in the standardization, things not always easy to regulate, and variations from which do not exert the same influence in the iodide assay.

Mention was made regarding ores on which an electrolytic-assay might be made accurately from a simple solution. Unfortunately such a method is not always permissible. Many elements and, except under nicely regulated conditions, even zinc and large amounts of iron, will cause errors. Except in the case of great excess of iron-salts, the errors are nearly all positive, and give high results. In all such cases the copper must be separated from the interfering elements. Usually the procedure is simple enough, but occasionally a high degree of skill is required. For these reasons the iodide method, with its almost unfailing accuracy, is usually preferable to the electrolytic. In this laboratory, where various ores of unknown composition are handled, it is customary to separate the copper out by an electrolytic assay, and in addition check the work by the iodide method.

To sum up, where no previous separation of the copper from interfering elements is necessary, the electrolytie is the preferable one of the three methods; otherwise the iodide is better. Under certain conditions the iodide method has been known to fail. In such cases it is left to the originality of the chemist to devise a method to fit the emergency. In the analysis of very rich gold ores, as in the case of the Mohawk ore running about 2% copper and 2% gold, results were from 0.25 to 0.50% high in copper by the iodide method. A simple filtration of the suspended matter previous to the addition of the acetic acid, preparatory to the titration, remedied the defect in the method. Such ores, however, are rare, and the liability of encountering interfering elements is much less in the iodide than in the electrolytic method.

The following are some results obtained in testing ore, tailing, and matte, by the three methods:

From the above it will be seen that there is no marked tendency for the iodide assay to be higher or lower than the electrolytic method. The cyanide results are usually the lowest of the three. More attention was given to the cyanide analyses than is usually the case. To secure a sharp end-point in the titration the bulk of the solution was kept low, in proportion to the copper present, and a standardization was made under exactly the same conditions.

It should be borne in mind, in comparing the iodide and electrolytic methods, that the danger of
interfering elements is much greater in an electrolytic than in an iodide-assay. The copper can almost always be separated by precipitation on aluminum, followed by hydrogen-sulphide water in a state pure enough for an iodide assay. This is less true of the electrolytic method, where often to assure accuracy a more elaborate separation must be made. The liability to error in standardizing an iodide solution, which is very remote, is more than offset by the loss in copper attending the removal of the cathode from the electrolyte, and to the error in weighing the same. In a well-equipped laboratory, on ores where no separation is required, the time factor is much in favor of the electrolytic method.

James W. Howson.

San Francisco, July 24.

Explosion in Compressed-Air Main.
The Editor:
Sir—I enclose a photograph illustrating the effects of an explosion of gas generated in the air-compressor of the Tonopah Mining Co. of Nevada. The pipe is 6 in. diam., and the contorted piece highest in the pile was bent completely back on itself in two places. The upper side as shown in the picture was the outside of the pipe. The explosion occurred in the Mizpah shaft on April 14 of this year. It was confined to the pipe between the surface and the 300-ft. level, wrecking all of it. A few minor timbers were torn out; aside from this no serious damage was done. The explosion did not extend back to the receivers or the compressor, nor to the pipe below the 300-ft. level, and fortunately the cage-tender was not within those limits.

The explosion was due to gas generated in the compressor-cylinders from the oil used in them. A few weeks after this explosion there was a similar one at the compressor-plant of the Standard Oil Co. in California, and today the compressed-air line of the Tonopah Belmont Co. exploded in the shaft, and on the surface. The cylinder oil used at both the Mizpah shaft and the Belmont shaft was supplied by the Standard Oil Co., and it is to be presumed that the oil used in their own compressor was the same. This series of explosions in such close succession constitutes a serious reflection on the quality of oil furnished by the Standard Oil Company.

Tonopah, Nevada, July 24.

Milling and Cyanide Practice at the San Prospero Mill, Guanajuato.
The Editor:
Sir—In J. S. Butler’s description of cyanide practice at the San Prospero plant, appearing in your issue of July 25, the curve sheets and tables showing the progress of extraction during the milling operation prior to the commencement of the cyanide treatment proper, make an interesting record. The table showing the extraction of values is as follows:

<table>
<thead>
<tr>
<th></th>
<th>Milling</th>
<th>Cyanide</th>
</tr>
</thead>
<tbody>
<tr>
<td>Gold</td>
<td>Extraction,</td>
<td>Extraction,</td>
</tr>
<tr>
<td></td>
<td>%</td>

<td>57.6</td>
<td>15.4</td>
</tr>
</tbody>
</table>

The extraction of the silver and gold content, 48% and 31.2%, in the crude ore during the pulping process in the battery is more remarkable when the conditions are analyzed. In a five-stamp battery of this mill, where the crushing-cylinder is 3.7 tons per stamp per 24 hr., 28.5 lb. of ore must be fed to each battery per minute, and a like amount (dry weight) of pulp must issue through the battery screens in the same time. As the amount of ore undergoing the pulping process within a five-stamp mortar will approximate 85 lb., it follows that the average time required for pulping the ore in the mortar would not exceed three minutes. During this time it is known that the size of the ore-pieces found at any time in the mortar will vary from the maximum size, 1½ in., to the portion of slime resulting from the pulping operations, and it is probable that 50% of the 85 lb. of ore always in the mortar box would be large enough to remain on a ½-in. mesh screen. What is remarkable is that one of this disproportion of sizes when submitted to contact with 0.12% KCy solution should yield 31.2% of its gold, and 4.8% of its silver content in three minutes. If the solution of silver and gold in the pulp would proceed at the same rate all the gold in the pulp would be brought into solution in four minutes and the silver in about 60 minutes. This is a more rapid rate of solution than is generally understood to be possible in connection with the cyanidation of ore, and the fact should attract the attention of those crushing ore in cyanide solution and stimulate investigation.

It would be interesting in this connection to know the character of the ore treated, and in what form the silver occurs in it. It is probable that a large portion of the silver exists as a chloride, for silver sulphide would hardly go into solution as rapidly as stated. At any rate the statement should open up a new line of investigation and research, the results of which cannot fail to benefit the industry.

Bernard MacDonald.

Guanajuato, Mexico, August 1.

The crushing strength of ice at 23°F. varies between 400 and 700 lb. per square inch.
MILLING PRACTICE IN NEVADA GOLDFIELD
REDUCTION WORKS.

Written for the Mining and Scientific Press
By E. S. Leaver.

The mill of the Nevada Goldfield Reduction Works at Goldfield is a custom plant, all ore being received through the sampling works. As the ores are sampled and purchased in small lots, this allows mill-results to be followed closely, and as the ores come from various mines and leases, including surface-dumps and deep workings, the results and treatment vary considerably. The surface, or oxidized ores, readily give high extraction by simple treatment. The sulphide ores require close attention, and in depth are becoming even more complex. The deeper ores, now being marketed, require close concentration, almost absolute sliming, and not less than 10 days' cyanide contact. The treatment consists in crushing wet by stamps, amalgamating on plates, concentrating on Wilfhey tables, fine-crushing of the sand in a tube-mill, re-amalgamation on plates, re-concentration on vanners, and cyaniding of the sand and slime.

The ore is crushed in weak cyanide solution (0.1%), and while this has been the practice for over a year, no particular effects are noted on the plates. The entire recovery has been better than formerly when crushing with water. The plates require more attention, but all pitting is avoided and the amalgamation has been good. By crushing in cyanide, treatment is favored, in that the ore is at once in contact with the solvent, and there is elimination of the loss of time in settling, decanting, etc. Also this practice avoids the loss in weak solution necessary in cyanide-plants where the ore is crushed in water or taken into the cyanide plant with water. In addition to the usual losses in waste-solution, the cost of water is an important item at Goldfield. Having only limited fall from the Wilfhey tables to the tube-mill, advantage is taken of Wilfhey tables as sizing machines, making three products, sand, slime, and concentrate. Only the sand is taken to the tube-mills, the aim being to grind it as fine as possible, and to favor passing as much of the finest sand as commercial treatment allows with the slime proper. As the ore in various mines differs, the percentage of slime and sand will vary, but approximately 20% of the original weight is treated as sand. This sand will pass the 100 mesh, and requires 10 to 20 days' double treatment by percolation, that is, the sand is collected and treated in an upper row of vats, discharged, and re-treated in a lower row of vats. Good success has attended the use of a substitute for tube-mill pebbles. The Danish pebbles were originally imported at a cost of about $60 per ton. A number of samples picked from medium low-grade ores were experimented with. The result was the finding of a close-grained compact ore which is an excellent substitute for the imported pebbles. Several tons of lumps can be selected from the ore in a short time. These lumps, varying in size, are fed into the mill, and in a short time it requires close inspection to detect them from the genuine imported pebbles. Results from these pebbles show a saving of $300 per mill per week.

The crushing or circulating solutions, after passing the concentrators, including the sand-collection vats, flow to large slime-collection vats, and the clear solution is taken off by rim-launders and decanters. This circulating solution then passes through its special zinc precipitation boxes, and is returned to the battery-tanks, to be again used under the stamps. When the slime at the collecting vats is at a proper specific gravity it is pumped to the treatment vat, where the strength of the solution is brought up if necessary. There it is agitated and aerated by circulation through centrifugal pumps, until the gold is in solution. This requires from 4 to 10 days. The slime is then separated from the gold-bearing solution by leaf-filters.

After a commercial failure with a well-known leaf-filter a number of experiments were made in the mill which led to the designing of a leaf which has given excellent results. The ordinary form or size of leaf was continued, but a filter was adopted that leaves no chance for clogging. This has been in constant use at these works for about one year, and has given perfect satisfaction. The canvas for the filter is sewed around the bottom and sides, making a bag about 5 ft. deep and 10 ft. long; the sewed edges are turned inside the bag; then, excepting about a three-inch strip along the sides and bottom, which is left for the pipe-frame work and suction, the entire filter is divided by stitching vertically in lines two inches apart, making pockets open at the top and bottom. Into these pockets are pushed grooved slats made of common lath. The grooves are about 7/16 in. deep and about 1/4 in. wide. Two grooves run lengthwise on each face, and each groove is placed so as to alternate with the groove on the opposite side, so as not to weaken the slats. Various experiments were made to determine the proper size of slat, number of grooves, etc., and the above was finally adopted.
Zinc fibre is used as a precipitant. The resultant product is roughly cleaned up, thrown into a small agitating-vat, and cut down by sulphurous acid. Sulphurous acid is a solvent for lime, zinc, and copper, making it preferable to sulphuric acid. Again, it is cheaper, and it appeals to the men directly handling the products, as they avoid the disagreeable stiute for tube-mill pebbles. The Danish pebbles are shipped in, and burned, the gas passing directly into the agitating-vat containing the zicky product and water in circulation. After the impurities are in solution, the fine gold and silver residues are drawn into a small filter-press, dried, and melted into bullion, which is sold to the United States mint.

RECENT CONCRETE TESTS.

At the Structural Materials Laboratories of the United States Geological Survey in St. Louis, Mo., important tests on the strength of plain concrete beams have just been completed. These form part of a comprehensive series of investigations undertaken by the Government for the purpose of determining the strength of concrete, plain and re-inforced.

Although it is true that concrete possesses but little strength in tension and must be re-inforced with metal to resist tensile stresses, it is believed that no study of concrete would be complete without a series of tests establishing its strength without re-inforcement. The tests reported indicate that concrete is unsuitable for use under conditions where it must resist tensile stresses, because of the small loads it will sustain and particularly because of the suddenness with which it fails, in striking contrast to the behavior of re-inforced concrete, which usually shows a gradual development of cracks preceding failure. These beam-tests cover 144 beams without re-inforcement 8 by 11 in. in section, and 13 ft. long, together with the corresponding compression-test pieces, consisting of cylinders 8 in. diam. by 16 in. long and of 6-in. cubes. An attempt has been made to bring out the comparative value of gravel, granite, limestone, and einders for use in concrete; the effect of age and consistency on the strength, as shown by the modulus of rupture of the long and short beams and by the ultimate strength of the cylinders and cubes; and the influence of age and consistency on the stiffness, which is indicated by the unit-elongation of the long and short beams and by the initial modulus of elasticity, as determined by tests of the cylinders. Three consistencies: wet, medium, and damp, were arbitrarily chosen. Tests were made at the ages of 4, 13, 26, and 52 weeks.

The effect of age is perhaps the most important, since an early attainment of considerable strength, and no subsequent decrease in strength, are two essential qualities in concrete. The least age at which any tests were made was four weeks, and at that period in no case except that of the einder-concrete, wet consistency, did the compressive strength fall below 2000 lb. per square inch, while the einder-concrete had in every case a compressive strength of at least 1000 lb. per square inch. The compressive strength shows a substantial increase from four to thirteen weeks, with the single exception of lime-stone-concrete mixed to a wet consistency, for which a decreased strength is indicated by the tests, a decrease which continues to the age of twenty-six weeks. This decrease in the strength of the lime-stone-concrete is unexplainable. The other aggregates show either the same or a slightly greater strength at twenty-six weeks than at thirteen weeks. The transverse tests on both the long and the short beams bear out the fact indicated by the compression tests on the cylinders and cubes, and lead to the belief that the tensile and compressive strength are affected alike by both age and consistency. In almost every case the concrete of damp consistency is the strongest and that of wet consistency the weakest. This is true for the three ages at which the concrete was tested, and is confirmed by the tests of the beams as well as of the cylinders and the cubes. Attention is called to the fact that the damp consistency used is much wetter than the damp consistency used in making mortar building blocks, for which the same conclusions may not apply.

The difference in strength of the stone and gravel-concretes of the three consistencies is more pronounced than in the ease of the einder-concrete. The effect of the consistency on the strength seems to depend to a great extent on the behavior of the concrete while being tamped and to the method used in tamping. Great care was taken to tamp all the concretes in the same manner. The thorough mixing of the concrete is absolutely essential and has a marked influence on the consistency. The relatively slight influence exerted by the consistency on the strength of einder-concrete may be partly due to the structural weakness of the einders themselves, which in the drier mixtures were to a great extent broken up by the tamper, while in the wet mixtures, the einders would move from beneath the tamper. While it is true that in almost every instance the drier mixtures give the greater strength, it does not follow that dry, or damp, mixtures should be used in construction. Practical considerations warrant the use of a wet mixture. The difficulty in securing efficient tamping and a smooth finish in a damp concrete, the loss of strength due to the unavoidable drying out of the concrete used above water, the difficulty of securing in re-inforced concrete an intimate union with the steel, and the far greater ease of placing wet concrete, all seem to warrant the sacrifice of what in many cases is but a slight difference in strength for a greater ease of manipulation and a thorough bedding of the steel, which is of the utmost importance in re-inforced concrete work.

The total Panama canal excavation since the American Government took possession, in May, 1904, up to the end of the fiscal year ended June 30, 1908, amounted to 40,988,575 cu. yd., which includes the earth moved from the canal prison and from accessory works. Of this amount 66% has been taken out in the last fiscal year.

The Austrian railroads, which have heretofore run on the left-hand track of a double-track roadbed, have now changed to right-hand running.
"Ye wouldn’t think McCarty t’ look at ut, that th’ piece iv quartz ye-er sittin on could be iv much interestin’ th’ annywan, but ‘tis so— Now kape quiet an’ don’t git excited, f’r ‘tis not high grade. It could just as well be th’ ither piece ye’ve bin throwin’ dirt at, f’r ‘tis ye tvenificial interest I’m rayferrin to.

Thim scientifick la-ads are a grate lot, an’ there’s no tellin’ what they’ll do next. ’Twould ma-ake ye laf sometimes t’ see what they’ll git all wor-ried up an’ excited about. Like as not if ye go into th’ labbertoory iv wan iv thim, ye’ll find him screwin’ his eye into a little brass toobe on a stand, that he calls a microscopy, au’ if ye ask ’im what he’s doin’, he’ll look at ye with pity, an’ sa-aay that ‘tis a grata-ate diskivery he’s just made.

“What is ut?” ye say.

“Why!” he says, ‘here’s a foime speeymen iv th’—’ anc’ he says a na-ame that makes ye dooble up ye-er flats till ye foin’d he’s not rayferrin t’ you.

“In plain English, what is ut?” ye ask.

“A fle,” he says. ‘An’ in th’ speeymen I’m now examinin in foin’d thar are twenty-three hairs on his left hind leg, while all th’ rest I have iv ever seen had but twenty-two.’

“Well, what of ut?” ye ask him.

“Why, ‘tis a grata-ate diskivery,” he says; an’ maybe some time I’ll have a new fleen named ather me.’

“Well,” ye says, ‘if that’s all that’s bitin’ ye, I’ll na-ame me dog after ye, an’ he’s full iv flees.’ But all th’ thanks ye get is a har-rd look.

“Av course th’ scientifick la-ads ar-re not a great this wan, but ‘tis a str-rong raysemblance there is between all iv thim.

Th’ la-ads that dayvote thair time chafely t’ studyin’ th’ rocks an’ talkin’ about it afferwards have bin pullin’ off raycently what they’d call a semy-nary if they’d bin all thegither; an’ ‘tis a foime lot iv la-ads, all iv thim.

There’s Voun Hi-ist, who still thinks they ma-ake sarpintine rock in Californy be stirrin’ wather an’ epsom salts tgether in a sand bank. There’s Rickard an’ DeKalb, who have stiddy jobs now writin’ f’r th’ pap’rs. There’s me frind Horse Winehell, who wor-rks on th’ raleorode f’r Jim Hill; an’ Emmons, who made th’ good guess at Leadville. An’ thin there’s Weed, who bate Emmons in print at Butte; an’ Lindgren, who’s got a job kapein books f’r Tiddy. There’s Kemp, who writes books f’r pocket money, an’ Wright, who borrows his principles fr’m Sorray; au’ Spur-r-r, who used t’ work f’r Dan-l-in-th’-lion’s-deu, befoor th’ Lord f’rgot ’im. An’ thin there’s me frind Turner, with his perknite—"

“What kind iv a night’s that?” asked McCarty.

“Tis a dar-rk night,” replied Murphy. “I’m surprized at ye-er ignorance.

Th’ la-ads put a bit iv rock in a microscopy, which is a sort iv nickle-in-th’-slot-masehen, an’ all ta-ake turns lookin at ut. Ye put in ye-er nickle an’ ye see a picture iv a crazy-quilt like ye-er gran’mither used t’ ma-ake.

“Wan iv th’ la-ads screws his eye into th’ brass toobe f’r a while, an’ thin raymar-rks that there be a small red patch in th’ upper left-hand corner, with a nick in wan soide. ‘Tis a sign,’ he says, ‘thot th’ wather cooms up in a mine fr’m th’ bottom.’ Anither la-ad takes a look. ‘There’s a small black speek just bellow th’ red patch,’ he says, ‘that has th’ corners rounded off. ‘Tis a sign that th’ wather cooms down fr’m th’ top,’ he says.

“I never was in a mine yet,” said McCarty, "where th’ wather didn’t coom down fr’rm th’ top before it were poumped up fr’rm th’ bottom.’"

“Anither la-ad steps up an’ looks in,” continued Murphy. “I ‘junge fr’m th’ appearance iv th’ yellow patch with th’ hole in th’ middle,’ he says; ‘that th’ wather cooms up fr’m the bottom first, an’ thin cooms down fr’m th’ top,’ he says. Wan more tood screws his eye into th’ brass toobe an’ says, ‘Th’ striped patch on th’ ither side indicates t’ me moind that th’ wather cooms in fr’m th’ soide,’ he says. Th’ la-ad Wright looks in. "Hurray!” he says. ‘Say—lute me saylnishun; ye-er all iv ye wrong. Th’ wather didn’t move at all,’ he says. An thin th’ la-ad Spur-r-r takes a squint. ‘Tis, as plain as th’ nose on ye-er fa-ace,” he says, ‘that th’ wather always cooms up fr’rn th’ bottom,’ he says. With that he takes another look. ‘I was not mistaken,’ he says; an’ could not be. Th’ wather always cooms down fr’rm th’ top,’ he says. After th’ next look, which is a good long wan, he says, ‘Tis proved beyond question iv a doubt, as I just raymar-ried, that the th’ wather is har-rd, an’ always cooms in fr’rn th’ soide, straight fr’rn th’ nearest volcymo,’ he says. An’ thin he strikes an’ attitude, an’ smiles like th’ Ray-poolbian pictures iv Willyum Chinnings Brine: ‘till th’ bye Horse, who’s a mischigvous la-ad, hits him in th’ eye with a strame fr’rn th’ fire hose, an’ ma-akes him f’rgit all that he’s said.’

“Where does Jawn Hammond say th’ wather cooms fr’rn?” asked McCarty.

“Well,” said Murphy. ‘Since th’ Raypooebian gave him th’ cold ba-ath, he’s had dommed little t’ sa-aay about anymthing.’"

**Butte uses 200,000 mining stalls annually.** About three-fourths of this number are secured from the Deerlodge National Forest west of the city. The Allen Company has purchased from the Government the timber which the Forest officers think can be removed with safety to the forest on an area of about 8000 acres, and it is estimated that they will secure about 50,000,000 feet, board measure, under this one contract. The Company also supplies the smelter at Anaconda with converter poles, and small cordwood to the public. The timber is almost wholly lodgepole—a tree of small size, but large enough for stulls, lagging, and converter-poles.

**Sudden enlargement** in the section area of a pipe running completely full of water, often causes more loss of head than an equal contraction. Changes in size of pipes should always be obtained by gradual transition.
MOISTURE IN THE ATMOSPHERE AND ITS EFFECT ON THE OPERATION OF COM-PRESSED-AIR MACHINERY.

By H. M. PrYneot Murphy.

*Ever since the introduction of compressed air into the railway and commercial fields, much imperfect operation and many failures have resulted from the presence of condensed moisture in vital parts of the apparatus used. Long practical experience and careful scientific investigation have, however, demonstrated that difficulties arising from this source may be reduced to comparative insignificance, if not entirely eliminated, by properly installing the various devices concerned. The objects of this article are to point out the physical laws involved in the subject, to explain the most approved methods of securing 'dry air' for use in any system, and to establish a correct method for determining the amount of moisture that is deposited by compressed air under various operating conditions.

The evil effects of an excess of moisture, if permitted in any system of condensed-air pipes, are very great. In warm climates, where freezing weather is never experienced, any water passing through and deposited in the various valves and passages is not a positive source of danger, although it may cause extremely sluggish and unsatisfactory operation, but it will inevitably produce a much more rapid deterioration of the apparatus than would otherwise be the case. On the other hand, in latitudes where freezing does occur, for even short periods of time, any water which is deposited in these systems is not only liable to burst pipes and valves, but also to obstruct the ports and passages of the various devices, and even to so entirely block the action of the moving parts, that failures from this source are, unfortunately, of frequent occurrence during the winter months.

In order to clearly understand the situation and to obtain a useful knowledge of the methods employed in practice to obviate the difficulties experienced from the presence of the moisture in the atmosphere, it will be necessary to first investigate the simple unvarying physical laws which govern the case. These laws may be stated as follows:

1. Atmospheric air always contains some moisture, which it absorbs from rivers, creeks, rainfall, and the like.

2. The amount of moisture present in the atmosphere depends on local conditions and on the weather.

3. The maximum amount of moisture that pure air can contain depends only on its temperature and pressure, and has an unvarying value for each condition.

4. The higher the temperature of the air, the greater is the amount of moisture that it can contain.

5. The higher the pressure of the air, the smaller is the amount of moisture that it can contain.

6. When air is compressed, its temperature rapidly rises to a high point, which depends on the design and speed of the compressor and the delivery-pressure worked against.

7. The rise of temperature due to the compression of the air far more than offsets the opposite effect of the rise of pressure on the moisture-carrying capacity of the air.

As a result of these laws, it is easy to see how water is deposited by compressed air as it passes from the pump to the various portions of the system. Suppose that a certain amount of atmospheric air enters a compressor, and that this air is at the saturation point, that is, that it contains all the moisture possible at the existing outside temperature and pressure. Then as this air is compressed as stated in law 7, its moisture-carrying capacity rapidly increases, for the rise of temperature more than offsets the opposite effect of the rise of pressure, consequently all the moisture in the air is still retained by it, and passes with it into the main, or storage-reservoir, and its connecting pipes. Now if this air is permitted to pass from here into the various parts of the system before being cooled to the outside-temperature, it will, of course, carry more moisture with it than it is capable of holding in suspension when the temperature finally drops to the normal point, and this excess quantity will then be deposited, because, the pressure being high, the air cannot hold as much moisture as it did at the same temperature and at atmospheric pressure (law 5).

Now, as will be readily seen, in order to reduce to a minimum the evil effects of this water, which is bound to appear in any compressed-air system under average weather conditions, it is most desirable to cause the air to deposit all of its excess moisture in the main reservoirs, from which it may be easily removed by the drain-cocks which should always be provided for that purpose. In order to accomplish this completely, it is merely necessary to cool the air to the outside temperature before it leaves these reservoirs. This may easily be done by using a sufficiently long air-discharge or radiating-pipe between the pump and the main reservoirs, which should be of large capacity, not only to provide for an ample storage of air, but also in order to allow the compressed air to remain in them for a length of time sufficient to permit the superfluous moisture to be completely deposited, and to insure a liberal supply of cold air at all times. The use of pressure-reducing valves between the main reservoirs and the rest of the system is sometimes considered of benefit in securing 'dry air,' but such devices simply cause some of the moisture to be deposited in the pipes near at hand (not in the main reservoirs), instead of in the more remote parts of the system, the merits of this method are extremely doubtful, and it should never be resorted to unless drain-cups are placed in the pipes concerned, for excess water-vapor, once allowed to pass from the main reservoirs, will surely cause ultimate trouble unless it be properly trapped and regularly drained off.

In stationary work, where the air is sometimes reheated before being used, in order to increase the efficiency of the devices operated by it, no trouble ought ever to be experienced from the moisture, but
TABLE I.—A TABLE WITH FORMULAS GIVING THE WEIGHTS, IN POUNDS, OF 1 CU. FT. OF DRY AIR, OF 1 CU. FT. OF SATURATED STEAM OR WATER VAPOR AND THE MAXIMUM WEIGHT OF WATER VAPOR THAT 1 LB. OF PURE AIR CAN CARRY AT ANY PRESSURE AND TEMPERATURE. (Copyright, 1908, by H. M. Prevost Murphy.)

</table>

The values K and H being given in the table for various temperatures, t, in Fahrenheit degrees, the formulas are:

Weight of 1 cu. ft. saturated steam = \( \frac{1.3253 K H}{459.2 + t} \) (exactly).

Weight of 1 cu. ft. saturated steam = \( \frac{1.3253 K H}{459 + t} \) (approximately).

H being equal to 2.036 \( \times \) (gauge pressure + atmosphere pressure, in pounds per square inch).

H, K, and t having corresponding values as given in table.
Weight of 1 cu. ft. pure dry air = \( \frac{1.325271}{459.2 + t} \) (exactly).

Weight of 1 cu. ft. pure dry air = \( \frac{1.3253}{459 + t} \) (approximately).

Weight of 1 cu. ft. pure dry air = \( \frac{2.698192}{459.2 + t} \) (exactly).

Weight of 1 cu. ft. pure dry air = \( \frac{2.7}{459.2 + t} \) (approximately).

\( M \) being the absolute pressure measured in inches of mercury.

\( P \) being the absolute pressure measured in pounds per square inch.

Letting \( W = \) the maximum weight in pounds, water vapor, that 1 pound of pure air can contain, when the temperature of the mixture is \( t \) and the total, or observed, absolute pressure in pounds per square inch is \( P \), the value of \( W \) is:

\[
W = \frac{K \cdot H}{2.036 \cdot P - H} \quad \text{(exactly)}.
\]

The values of \( K \) and \( H \) corresponding to the existing temperature being given by the table.

For any temperature the value of \( K \) (the ratio of the weight of a volume of saturated steam to an equal volume of pure dry air at the same temperature and pressure) may be accurately computed by the following formula:

\[
K = 0.6113 + \frac{0.092 \cdot t}{850 - t} \quad \text{(exactly)}.
\]

Note.—The results obtained by the use of any of the above formulas agree exactly with the average data for air and steam weights as given by the most reliable authorities and careful experiments, for all pressures and temperatures; the value of \( K \) being correct for all temperatures up to the critical steam temperature of 659° Fahrenheit.

In all other installations, including those on railways, long radiating pipes should always be employed. Of course it is true that even if the compressed air be cooled to the existing outside temperature, before leaving the main reservoir, some moisture may be deposited in the rest of the system if a drop of the outside temperature occurs, but the amount of water thus thrown out must obviously be small, and it appears merely as little beads on the interior walls of the various devices. It is seldom that any trouble is experienced from this source alone. Moreover, although compressed air may be properly dried before leaving the main reservoirs, some moisture may be temporarily deposited when the air is subsequently expanded to lower pressures, as the moisture-carrying capacity of the air is usually affected more by the drop in temperature, resulting from the expansion, than by the drop in pressure, but when the air again attains the outside temperature, the moisture thus deposited will be re-absorbed if it is freely exposed to the compressed air.

In order to determine exactly what percentage of moisture pure air can contain at various pressures and temperatures, to ascertain how low the ‘relative humidity’ of the atmosphere must be in order that no water will be deposited in any part of a compressed-air system, and also to find to what temperature air drawn from a saturated atmosphere must be cooled in order to cause the deposition of moisture to commence, the following discussion is necessary, as no correct method has heretofore been published to cover the situation.

In order to obtain the desired information, it is only necessary to remember a well-known physical law which covers the case of most mixed gases with great exactitude, for water-vapor is merely a gas. This law is known as ‘Dalton’s Law of Gaseous Pressures’, and may be stated as follows:

Every portion of a mass of gas enclosed in a vessel contributes to the pressure against the sides of the vessel the same amount that it would have exerted by itself had no other gas been present.

In other words, the total pressure exerted against the interior of a vessel by a given quantity of a mixed gas enclosed in it is the sum of the pressures which each of the component gases would exert separately if it were enclosed alone in a vessel of the same bulk at the same temperature. This law applies to mixtures of pure air and saturated water-vapor, and in order to determine the maximum weight of moisture that can be held in suspension by one pound of pure air at any temperature and pressure it is merely necessary to proceed as outlined below. Letting \( p_2 \) represent the absolute pressure in pounds per square inch, and \( t \) the temperature Fahrenheit; the weight in pounds of 1 cu. ft. of pure air is known to be equal to:

\[
2.698192 \times \frac{p_2}{459.2 + t}
\]

Also letting \( N \) equal the volume in cubic feet of one pound of pure air at the temperature, \( t \), and pressure, \( p_2 \), there results the equation:

\[
1 = N \times 2.698192 \times \frac{p_2}{459.2 + t} \quad \text{...(Equation 1)}
\]

Now \( w \), the weight in pounds of 1 cu. ft. of saturated steam (or water-vapor) at the temperature, \( t \), and corresponding absolute pressure, \( p_1 \), in pounds per square inch, has been shown by the author to be accurately expressed, in accordance with the average values given by the most reliable authorities, by the following equation, for all conditions:

\[
w = \frac{p_1}{459.2 + t} \left( 1.6494 + \frac{0.248 t}{850 - t} \right)
\]

and by letting \( W \) represent the weight of \( N \) cubic feet of saturated steam at the temperature, \( t \), and pressure, \( p_1 \), there results the equation:

\[
W = N \times \frac{p_1}{459.2 + t} \left( 1.6494 + \frac{0.284 t}{850 - t} \right) \quad \text{...(Equation 2)}
\]

By taking the \( N \) cubic feet of pure air at pressure, \( p_2 \), and the \( N \) cubic feet of saturated steam at the pressure, \( p_1 \), and forcing them both into one vessel of volume, \( N \), keeping the temperature constant at the value, \( t \), the resulting pressure. By Dalton’s law, will be \( p_2 + p_1 \), which may be placed equal to \( p \), thus:

\[
p = p_2 + p_1 \quad \text{...(Equation 3)}
\]

\( W \) will, of course, represent the maximum weight of water-vapor that 1 lb. of pure air can contain under the given conditions of pressure and temperature,
as the steam considered is at the saturation point. To obtain the desired formula which will express the value of \( \Delta W \) in terms of the known quantities it is merely necessary to divide the members of equation 2 by those of equation 1, thus:

\[
\frac{N \Delta p_1}{W} = \frac{1.6494 + 0.248 t}{459.2 + t} \cdot \frac{p_1}{p_t}
\]

which may be simplified by division to give,

\[
W = \left[ 0.6113 + \frac{0.092 t}{850 - t} \right] \frac{p_1}{p_t}
\]

but (by equation 3) \( p_1 = p - p_t \), and by substituting this value of \( p_1 \) in the above equation there results:

\[
W = \left[ 0.6113 + \frac{0.092 t}{850 - p - p_t} \right] \frac{p_t}{p_t - p} ; \text{ or,}
\]

\[
W = \left[ 0.6113 - \frac{0.092 t}{850 - 2.036 p - H} \right] \frac{p_t}{p_t - p}
\]

... (Equation 4)

where \( H \) represents the tension of saturated steam (or water-vapor) at the temperature, \( t \), in inches of mercury.

**Table II.**—Weights, in Pounds, of Pure Dry Air, Water-vapor, and Saturated Mixtures of Air and Water-vapor at Various Temperatures, Under Normal Atmospheric Pressure of 29.921 in. of Mercury or 14.692 lb. per sq. in. Also Values of the Elastic Force or Pressure of the Air and Vapor when Present in Saturated Mixtures. (Copyright, 1908, by H. M. Prevost Murphy.)

</tbody>
</table>

In order to simplify matters, the first member of equation 4 may be placed equal to \( K \), thus:

\[
W = \frac{K \times H}{2.036p - H} \text{ ... (Equation 5)}
\]

The values of \( K \) and \( H \) corresponding to all ordinary temperatures, are given in Table I; that is, equation 5 is the desired simple formula which gives the maximum weight, \( W \) (in pounds) of water-vapor that one pound of pure air can contain when the total or observed absolute pressure in pounds per square inch is \( p \), and the values of \( K \) and \( H \) correspond to its existing temperature, whatever its value may be. Table I will also be found of much practical value in other connections by noting that \( H \) is simply the absolute pressure of saturated steam expressed in inches of mercury, the absolute pressure in pounds per square inch being readily found for any desired temperature by dividing the values of \( H \) by 2.036; also \( K \) represents the ratio of the weight of 1 cu. ft. of saturated steam at any given temperature and corresponding pressure to 1 cu. ft. of pure air at the same pressure and temperature.

It is worthy of note, as demonstrated in the preceding discussion, and as proved by numerous experiments, that the ratio just referred to is not a constant, but has a different value for each temperature; consequently all of the tables heretofore published in text-books and hand-books which give the relative and total weights of air and water-vapor and of the mixture, and which have been computed on the erroneous assumption that the ratio in question is a constant, are not to be relied on. The majority of the values furnished by such tables are far from being correct. Table II, given in this article, is figured correctly by the use of the exact ratio for each temperature specified, and should prove of value in all moisture computations.

Columbite and tantalite are generally confused in this country. A sharp distinction is drawn between them in England and Europe, columbite being a niobate of iron, while tantalite is a tantalate of iron. Between these two FeNbO₃ and FeTaO₃, neither of which is ever found absolutely pure, all gradations from one into the other occur, and manganese is generally present, replacing a portion of the iron. Therefore Dana gives the formula (FeMn)(NbTa)O₄. There is no market for cobaltite, but tantalite containing 40% or more of the taltalic acid (Ta₂O₅) is salable on special negotiation. There is no steady demand, but it may be said in a general way that tantalite containing 40% Ta₂O₅ is always worth as much as $100 per ton at tide-water.
THE GENESIS OF THE COPPER ORES IN
SHASTA COUNTY, WEST OF THE
SACRAMENTO RIVER.

Written for the Mining and Scientific Press
By William Forstner.

The deposits of copper ore in Shasta county, California, are in the northwestern part of the county. They can be subdivided into two belts, the Iron Mountain belt west, and the Bully Hill belt east of the Sacramento river. In both these belts the ore deposits are in the form of massive pyritic bodies, contained within acidic extrusive rocks. In the Iron Mountain belt are two pre-middle Devonian extrusives, the Copley andesite and the Balaklala rhyolite; the latter containing the copper-ore deposits. The rhyolite is undoubtedly later than the andesite, and the latter may underlie the area covered by the rhyolite. Both were extruded on land. The underlying rocks are probably the older schist-series found in Trinity and Siskiyou counties.

The Balaklala rhyolite consists of various flows which might be differentiated in the underground works by careful study, in order to decide whether the orebodies are confined to one or more flows, or are distributed through the entire rhyolite mass. Although the rhyolite is not homogeneous the following description affords a basis for further discussion. The rock is, throughout, considerably altered. Its principal primary constituents are quartz and orthoclase, occasionally plagioclase. There is also an entire absence of feme minerals. The secondary principal constituent is quartz, and the secondary accessory constituents are pyrite, calcite, sercite, and kaolin. At a distance from the orebodies the pyrite generally occurs in small aggregates of minute grains, occasionally forming bunches, which latter generally consist partly, if not principally, of chalcopyrite. Well-developed cube pyrite is very rare. Close to the orebodies the country rock becomes pitted, and the cavities are to a greater or less extent filled with pyrite, until the material changes into massive pyrite, with small inclosures of quartz. The transition zone is generally from one to two inches wide. D. F. Campbell, in the Mining and Scientific Press, January 5, 1907, p. 28, mentions the presence of melas and chlorite, the latter often in such quantities as to give a dark-green color to the rock. I presume his specimens were collected near Iron mountain. In none of my specimens, collected between Motion and Backbone creeks, was chlorite detected microscopically. Possibly the green phases of rhyolite represent the Copley meta-andesite, which contains considerable chlorite.

The orebodies consist of massive aggregations of grains of pyrite with accessory chalcopyrite. These sulphides have entirely replaced the feldspars, and also part of the quartz of the country rock. Rhyolites contain from 21.8 to 47.8% quartz (Prof. Paper No. 14, U. S. G. S.), while generally the ores contain about 5% silica, consequently a replacement of quartz by sulphides must have taken place on a large scale. A similar case occurs in Butte, Montana, where the quartz of the granite, which is chemically analogous to rhyolite, is removed, resulting in large masses composed entirely of metallic minerals (S. F. Emmons, Trans. A. I. M. E., Vol. XVI, p. 57). Newman considers this replacement to be a chemical process, the removal and deposition proceeding simultaneously, molecule for molecule (‘Genesis of Ore Deposits’, p. 592). Sulphides of iron, copper, zinc, etc., are soluble in alkaline sulphide solutions, and also in alkaline carbonate solutions containing hydrolysulphuric acid (Van Hise, Mon. No. 47, U. S. G. S., p. 1106). There is little to be found in the literature of the genesis of ore deposits concerning the action upon quartz of solutions containing alkaline sulphides or carbonates, and carrying dissolved metallic sulphides, sulphites, and sulphates. As the orebodies were formed within fractured portions of the country rock, they were formed within the zone of katamorphism, and below the belt of weathering, consequently in the belt of cementation. The principal reactions in the lower part of this belt are cementation and metasomatism. The cementing substances are oxides, carbonates, silicates, and sulphides. Of the former, silica is the most important. In this case the composition of the circulating waters must have been such as to produce extensive metasomatism, causing the dissolution of the feldspars and most of the quartz of the rhyolite, and their replacement by metallic sulphides.

Our imperfect knowledge of the chemical activity of thermal waters under the influence of high temperature and pressure is yet an obstacle to the clear understanding of their work in depth. Chemists agree that silicea generally exists in the hot mineral waters in a colloid solution; and consequently does not diffuse through the rock-walls, which form semi-permeable membranes (W. Lindgren and F. L. Ramsome, Prof. P., No. 57, p. 220; and others). The thorough elimination of the rock constituents, mainly feldspar and quartz, shows that alkali and calcium carbonates and an excess of carbon dioxide were present. The presence of calcium carbonate is probable, as calcite replaces quartz, which is dissolved by waters containing alkaline carbonates, a corresponding quantity of calcic carbonate being deposited in its place (‘Genesis of Ore Deposits,’ p. 525). Sericite, with free silica and potassium silicate, result from the decomposition of orthoclase by the action of water alone at high temperature and under pressure (‘Geochemistry,’ p. 511); it also forms from quartz, in which case a complex chemical action is probably involved, a transportation of potash and alumina must be assumed (‘Genesis of Ore Deposits,’ p. 528). It must be kept well in mind that the solutions necessarily must have been very dilute. Alkali carbonates at high temperatures are readily soluble in water; at 135° C. 100 parts of water dissolve 205 parts of K₂CO₃, and at 105° C. 45.1 parts of Na₂CO₃; calcium carbonate, however, requires a great amount of water. At 21° C. it takes 1015 parts of water saturated with carbon dioxide to dissolve one part of CaCO₃. Silica also requires considerable water; it is soluble in 1000 parts of pure water. When precipitated from alkaline silicates, by water saturated with carbon dioxide, one part of silica requires about 5000 parts of water; but if the silica is set free in
sufficient water to retain the silica, one part of silica can thus be held in solution by 100 parts of water.

As stated above the ore deposition took place in a zone of fracturing of the rhyolite, in the lower portion of the zone of katamorphism; the fissures through which the waters circulated were most probably exceedingly minute, the chemical action of substitution must have taken place very slowly, and it may be accepted that the entire deposition covered a long space of time. The microscopic study of the material of the orebodies and of the immediate wall-rock confirms this view, as in some specimens the pyrite is crushed, while in others such is not the case, indicating that movements had occurred in the intervening time. It then appears probable that the deposition of the orebodies was the result of a double process, first, a replacement of the feldspars and silica by means of alkaline carbonates and carbon dioxide, and then a replacement of the alteration-product by metallic sulphides by means of alkaline sulphides and hydrogen sulphide. The iron content of these solutions must have been derived either from the underlying strata, or from the residual magma, fermen mining being absent in the Balaklala rhyolite. It must be remarked that, as yet, no bodies of copper ore have been found in the Copper meta-andesite, although it is a locus of many gold-quartz veins, among which are those at Old Diggings. At the head of Motion creek, on the line of the Iron Mountain copper-belt I have found some highly altered rock, most probably derived from basic rock; this may give a lead, especially considering that the pyritic ores at Black Diamond are close to serpentine and diabase, and those at Bully Hill to basalt.

In the orebodies under discussion the pyrite is found occasionally surrounded by narrow rims of quartz, but is not associated with chlorite or epidote. The rocks have not been metamorphosed to such an extent as to justify the assumption that dynamo-chemical metamorphism has taken place, and we are thus brought to the conclusion that the orebodies were formed by hydro-thermal processes, that is, by the action of ascending thermal waters (W. Lindgren, 17th. Ann. Rep. U. S. G. S., pp. 90 to 95). The form and the size of the orebodies vary greatly; some are lenticular, others have a more tabular form. Some have been entirely eroded, leaving only the outline of part of their walls as testimony to their former existence; of others only a relatively small residual mass of limonite remains. They must have formed in zones of intense fracturing of the country and were most probably limited by subsequent cross-movements, which by attrition caused impervious belts whereby the circulation of the solutions was circumscribed within certain portions of the zones of fracturing (R. H. Sales, Economic Geology, Vol. III, p. 329). These may be contraction-fractures, or they may have been caused by dislocation of the strata. I am inclined to believe that the original fractures, wherein the ore deposits formed were contraction-fractures, while the fractures which caused the formation of impervious clayey strata, in many cases limiting the ore-bodies, were the result of earth-movements. The latter, however, were not limited to the period of ore deposition, but persisted afterward, as proved by the faulting of some of the orebodies.

THE PASSING OF THE TAILING-WHEEL.

*The tailing wheel, that familiar object on the landscape at the Rand, has long been threatened and is now quietly passing from our midst. For a long time the mechanical engineers of the various groups of mines—notably A. M. Robeson, of the Corner House—were experimenting with various forms of elevators and pumps, but the actual displacement of the tailing-wheel can now for the first time be chronicled.

It has been ousted by an improved type of centrifugal-pump, evolved after lengthy and careful experiment by the mechanical engineering department of H. Eckstein & Co., to whose initiative Rand metallurgical practice owes so much. The history of the experiments is interesting. When the tailing-wheel of the Rose Deep broke down last year a centrifugal-pump was used temporarily to replace it. A fatal flaw in the centrifugal-pump was found to be the speed with which the manganese steel liners wore out, and also the large waste of power. These were eventually overcome by replacing with locally-made east white-iron liners, and by intelligent design, with such satisfactory results that the general adoption of this device is now only a question of time. In operating the centrifugal-pump possesses no advantages over the tailing-wheel; but in capital expenditure or prime cost, a marked saving is effected. The cost of a pair of pumps is, roughly, £1780; the usual cost of a tailing-wheel is £8000. For small equipments the difference in favor of the centrifugal-pump becomes more apparent than for larger ones.

The centrifugal-pump is notoriously inefficient, but its failings in this respect are greatly exaggerated. With sand the average efficiency is 40 to 45%, and it is hoped to obtain an efficiency of 50%, which nearly approaches that of modern high lift centrifugal-pumps. The centrifugal-pump has already displaced the tailing-wheel at the Rose Deep and the Crown Deep, at both of which mines the tailing-wheel has now been finally 'scrapped.' At the New Heriot a plunger-pump has been scrapped in its favor. At the Village Main Reef, one has been erected as a stand-by, and two pumps are being erected at the Glen Deep and two at the Durban Roodepoort Deep. At all the mines that have adopted the pump, duplicates will be erected. It is noteworthy that the life of a tailing-wheel averages only 12 years, and many of the wheels on the outop-mines and first row of 'deeps' are now nearing their end.

Radium exists in the sea water around the coast of Ireland in special abundance, according to some experiments recently carried on. The deep-lying sediments of the ocean were found to be exceptionally rich in this metal.

Nitro-glycerine freezes at 42 to 46° Fahrenheit, but is not entirely safe even when frozen.
THROUGH THE BOLIVIAN HIGHLANDS.

Written for the Mining and Scientific Press
By E. F. Mathewson.

(Continued From Page 288.)

Next morning a special mixed train goes a few miles up grade to Pulacayo, where the famous silver mine of that name is situated. Here is a great settlement dependent entirely on the mine and ruled with a rod of iron by the officials of the company.

The main entrance to the mine is by a tunnel which is lined in dangerous places with cut stone. The tunnel goes entirely through the mountain, a distance of about two kilometres, and the main shaft has its collar on this level. The ore comes out on the Pulacayo side, where it is hand sorted by women, making three grades as follows: No. 1, shipping ore, carrying 75 oz. or more of silver, which is sent to the United States; No. 2, smelting ore for Playa Blanca, carrying 60 oz. or over; and No. 3, amalgamating ore of less than 60 oz., treated at Huanchaca. The ore is all shipped in bulk. It contains considerable quantities of zinc and sulphur, a little copper, antimony, arsenic, and some lead, but its chief value is in the silver.

The mine is in charge of American and French mining engineers and is kept up in good shape. It is expensive pumping and hoisting with coal at twenty dollars per ton, and at an elevation of 15,000 ft. Electric power has since been introduced. The lower levels are hot, and the mine water is also hot, and the ground shifts and souses considerably. The ore is chloridized in hand roasters fired with laquía, followed by pan amalgamation. The plant was re-modelled by the late Arthur Wendt, after the style of the Butte, Montana, silver mills.

The journey from Uyuni to Oruro is not very interesting. The road is laid on the pampa or high plateau. At times one passes close to the mountains, and at Poapo, near the great lake of that name. At Challapata is seen tin concentrate ready for shipment to Europe, and near Oruro the dumps from prospect holes for tin are visible from the train. At Machaenamarea is a little establishment for tin and silver separation. The ore is finely broken by women with hammers, then roasted with salt in adobe furnaces, then leached and the silver precipitated as sulphide. The leached ore is then concentrated for tin in hand jigs, the concentrate or barilla running up to 75% tin.

Oruro is a regularly built town on slightly rising ground, at the base of a round hill in which is the famous San José silver-tin mine. Oruro was the terminus of the railway for years.

I visited the site of the old Catalan forge used by the Spaniards 300 years ago. It stands on the side of the hill in which the San José mine is situated.

There were the remains of 13 furnaces, the slag amounting to several thousand tons, averaging, by analysis of a sample, Pb, 31.83%; SiO₂, 30.0; CaO, 1.8; Fe, 10.0; Al₂O₃, 3.0; Sb and Sn, 3.5; S, 1.2; and the silver content was 15 oz. per ton. This slag was being shipped to the Playa Blanca smelter at Antofagasta for its lead and silver contents. The Spaniards scorified the lead until it was all removed as slag and there remained a plate or plancha of silver, which they cooled in the furnace and afterward cut up with chisels. The early coinage in Peru (at that time including what is now Bolivia), was made from long bars of silver chiseled from the plates above mentioned, roughly rounded by hammering, then cut off and trimmed to weight and stamped with a cross, the arms of Spain, and the date. Some of this old money is still to be obtained in Bolivia and Peru by inquiry for moneda antigua plata Cruz. The San José mine is owned by Bolivians and Scotchmen. It
has produced large quantities of silver in its day. There are now competent European mining engineers in charge who are introducing modern methods of mining and concentrating. The ore is hoisted in rawhide buckets, pounded up on anvils by Indian women using small hammers, sorted into first and second class, and the second class concentrated on hand-jigs and Wifley tables. The mine is on the side of the hill farthest from Oruro, but the old Spanish workings were on both sides and are shown in back of the church.

The trip from Oruro to La Paz was made in a special coach drawn by four mules, and driven by a young Scotchman only a few months out from the old country. The springs of the vehicle were wound with rawhide. The mules were changed at regular intervals, but no attempts were made to have harness to fit the different mules, the same sets going right through, and many of the mules were severely chafed by the misfitting collars. The road is fairly level, but is covered with small stones which are used to advantage by the llama drivers in their slings. These llama drivers, and in fact, all Bolivian Indians, men, women, and children, carry slings and use them with great accuracy. They turn the llamas with them as a cowboy turns his herd of cattle with his revolver. They fight with them also, and during a recent revolution they did great execution. The Bolivian Indian is peculiar in his ideas of honesty. If you contract with him to freight valuable goods, say from the mountains to the coast, a distance of 300 miles, he will carry out his contract to the letter and deliver everything to the last pound in good order. If you allow him to enter your house or camp he will steal anything he can lay his hands on without the least idea that he is doing wrong. He is fond of music and has several peculiar musical instruments. One is a very long flageolet made of bamboo; another, a kind of guitar, the back of which is usually the shell of an armadillo.

Some religious celebrations seen on the journey to La Paz were very interesting. The men and women dress up in amazing costumes, and perform all kinds of fancy dance-steps. Of course some alcoholic refreshment is furnished, with the usual result. The men have a peculiar head ornament which they regard with as much veneration as a freshman does his first dress suit. It is made of long feathers like peacock tail feathers, the quills fastened in a band to fit about the head. The feathers tower straight up from the head three feet or more, opening out a little like an umbrella upside down. This head dress is worn only on solemn occasions, such as these feast days. The women dress in tight's and wear wonderful bonnets.

First night out is passed at Sica-Sica. What it means I cannot say, but it is the plural of Sica. Many words in South American Indian languages form their plural by duplication. Sica-Sica is a little adobe village with a public square, absolutely bare. In hunting about the village I came across some curious ponchos, silver spoons, maté pots, and one peculiar pestle and mortar. Maté is a favorite drink in South America. It is made by steeping the leaves of the yerba maté in hot water and adding a little lemon rind for flavor. It is taken through a tube, with strainer on one end to keep out the leaves, called a bombilla, or little pump. The taste is decidedly herbaceous. The Bolivians always carry a stimulant in the form of coca leaves, from which the cocaine of pharmacy is obtained. These leaves they carry in a little pouch with some alkaline paste hardened into a cake. They chew the leaves with the alkali just as tobacco is chewed. There are many theories as to the action of the cocaine in the system when taken in this manner. The drug takes away the desire for food, at the same time stimulating the muscular system so that great tasks can be performed without fatigue. Certain it is that these people eat very little during long journeys, and they climb mountains at great elevations without difficulty.

All Bolivian Indians, men, women, and children, carry with them a kind of spinning wheel, with a long stem. They pull wool from the llamas as they need it and set the little wheel spinning thread at every convenient stop. Some are so expert that they can spin the thread while walking along. In some parts they have little clay saucers in which to spin the little wheels.

La Paz is in the bottom of an arroyo a mile wide and 1000 ft. deep. It is a good sized city with red tiled houses. In sight of the town are some of the highest peaks of the Andes; Sorata, 21,500 ft., and Illimani, 21,030 ft. snow-capped all the year round. There is a pass at the side of Sorata that is 17,000 ft. above sea-level. An interesting gold placer country lies to the east and west of Sorata. American capital is engaged in gold mining in both districts. There is a quaint hotel in La Paz, overlooking the main plaza. It must have been built over a hundred years ago. The walls are several feet in thickness and resemble those of a fortress. We met here Professor and Mrs. Baudelair, who had spent several years on the Island of the Sun in Lake Titicaca, studying the Inca remains. Professor Baudelair had made numerous trips for the American Museum of Natural History of New York, and his collections are included in the Peruvian section of the museum.

There is a tribe of Indians chiefly in the neighborhood of La Paz called the Aymaras, totally distinct from the Quechus that occupy the greater part of Bolivia and Peru. The Aymaras are said to be cannibales, and stories were told of their sucking blood from dying men after the big battle of the revolution of 1899.

The men dress in dark blue homespun cloth suits, consisting of tunic and trousers, the latter somewhat
resembling the Zouave costume. They have the cloth cut away back of the calves of the legs in a V shape, the V being filled loosely with muslin. This is to give freedom to the limbs in walking and running. They wear a kind of toque, usually red in color and

much resembling the toque worn by the French Canadian habitant.

The Aymaras are supposed to be descended from a tribe that occupied the territory prior to the advent of the Incas.

There are many curious things to be seen in the markets and stores of La Paz, such as rubber 'biscuits' from across the range which are shipped to La Paz and transshipped to Europe or the United States; coffee of Yungay, said to be the best in the world; peculiar fish somewhat like brook trout that are taken in Lake Titiaca. Along with these are German aniline dyes which are rapidly replacing the permanent colors of the natives; German shawls which the Indians like better than their own homespun, and other imported articles. The German cut does the English and Americans as traders in foreign countries. The foreigner has his own notion of what he wants, and the German will get it for him exactly as he wants it; and at any price he may thrown at the mules whenever the driver wishes to encourage them to fresh exertion. The stage reached Puerto Perez in the midst of a heavy thunder-storm late in the afternoon, and after a little rest and an inferior meal at the little hotel, I took passage on the small steamer that went during the night diagonally across the lake, a distance of 80 miles, to Puno, in Peru. The night was beautiful, and fortunately there was not much wind, otherwise my impression of steamboat travel on the highest navigable water in the world would have been different. They said that it was frequently very rough, and if one became seasick it was a serious matter, owing to the difficulty in breathing the rarefied air at an altitude of 12,500 feet. The first steamer for Lake Titiaca was built in Scotland and brought over in sections. It was packed on mule-back from the coast to

the lake before the railway was built to Puno. It took three years to get all the pieces up from the coast. The later boats came in sections of larger size by rail. I arrived at Puno, Peru, in the early mor-
ing, and it was a perfect day. On nearing the landing places I noticed many native canoe-like rafts built of reeds tied in bundles and shaped very like the birch bark canoes of the North American Indians. These canoes had sails of reeds also. Mt. Sorata looms up to the east in grand style, showing its white cap far above the rest of the range. The customs officers inspected the baggage, but gave little annoyance.

Puno is distinguished for several things. It has the highest cathedral in the world, 12,540 ft. above tide. It has torrential rains, so the cobble-paved streets are sunk a couple of feet below the sidewalks, and stone-arch crossings are made at intervals. Hence cart travel is out of the question. The copper from Coro Coro is shipped up the Desaguadero river to Lake Titicaca, and thence to Puno, where it is loaded on cars for the coast.

The ride from Puno to Arequipa is a novel experience. After leaving Puno the grade is ascending until the summit, Crucero Alto, 14,666 ft. above sea, is reached; then a rapid descent is made to Arequipa, 7550 ft. The railway cuttings, through what looks like volcanic ash, resemble the cuttings in snow-banks, excepting that the color is light buff, instead of white. The marks of the shovels are exactly the same. At one point in the descent can be seen four different levels of the track below, thus showing the tortuous nature of the construction. Near Arequipa is seen the Misti, a beautiful volcanic cone on which Harvard University has established an observatory which it has maintained for many years. Arequipa is famous for its religious festivals and for its churches; also it is noted for earthquakes, of which it has a constant supply on hand. In the ‘Grand Hotel Central’ I found many evidences of earthquakes in the building. It seems that the last great earthquake knocked down the upper stories of all the houses in the city, and the people were too poor to re-build, so they simply roofed in the lower stories and contented themselves with smaller houses. In many parts of the city the ruins of old walls are visible. As in most South American towns, there is a Foreign Club, where one meets all the prominent merchants and railway officials. Visitors are welcomed and treated royally.

On the outskirts of Arequipa are signs of agriculture, but the land is very uneven and hard to cultivate, and the supply of water for irrigation is limited. The train passes closely by an ancient aqueduct not far from the town, plunges through a canyon and then out on a sandy plain, from which point the journey is practically through a desert.

The port of Mollendo is a misnomer. It is only an anchorage exposed to the prevailing winds and swell. It is frequently so rough that the vessels have to wait over a day to land passengers. The following day I boarded the steamer, one of the Pacific Steamboat Navigation Co.’s fine boats, and proceeded south toward Antofagasta. To give an idea of the difficulties of securing laboratory supplies in this part of the world, this incident is worth recording. Acids in Winchester bottles are shipped to the West Coast from Europe. The cases containing the bottles are always carried on deck. If the slightest leak shows in the package the whole case goes overboard. I saw thrown overboard, at Mollendo, several cases of acid because one bottle had evidently broken and the leakage from it had stained all the other packages. The coast steamers are very comfortable; the cabins are large and the staterooms spacious. The meals on the Pacific Steam Navigation Co.’s boats are in the English style. Those on the Chilean line are also good, but in Chilean style, to which the average American takes some time to get accustomed. Traders occupy the space between decks with a mixture of bananas and oranges from Guayaquil; chickens, turkeys, ducks, eggs, vegetables and fruits, baskets, emboidery, wooden kitchen utensils, and confectionery. The whole northern part of Chile from Huasco to Arica, including the thickly settled portion about Iquique, has to be supplied with everything edible for man and beast by the steamers and their traders. The steamers usually travel at night and make a port or anchorage in the morning. There is no port on the west coast at which the steamers tie up to a wharf except Callao. Even Valparaiso is only an anchorage.

At Arica appears the famous hill over which the Chileans drove the Peruvians during the last war. With the aid of a powerful glass one can see at this point the remains of the good ship Watterer. This old style United States gunboat was carried a mile inland when the great tidal wave did so much damage along the west coast. She was dropped right side up without injury on the pampa. The sailors went on with their regular duties for some weeks until another United States vessel came along and
took them off, together with the valuable part of the equipment.

Another port of interest is Caleta Buena, from which much nitrate of soda is shipped. The coast range back of which the nitrate is found comes to the water's edge at this point. The nitrate is lowered in three stages by balanced elevators to the little strip of a town at the foot of the hill, and there put in lighter and sent out to the ships.

The next stop is Iquique, where one can go ashore and get a meal at the cozy little resort, a mile out of town, called Carvancho. The features of Iquique harbor are the forty or more sailing vessels always at anchor there, and the great flocks of pelicans on the rooks near the shore. Iquique is the largest nitrate port in the world. There is a railroad running to the Pampa and extending north and south to reach all the nitrate oficinas. There has been so much nitrate spilled about the streets of Iquique that in case of a serious conflagration they have to be careful that the dirt of the street does not catch fire. Nitrate is a dangerous cargo, for if mixed with a little carbon, such as coal dust left from a previous cargo and a light applied, nothing can save the vessel.

The next stop of importance is Tocopilla, where a little copper ore is loaded for the smelters at Antofagasta. Finally the steamer reaches Antofagasta, where I bid farewell to the captain and other good friends on board, take to the whale boat and cross the bar, escaping a ducking only by the good judgment and skill of the boatmen.

The purification of bauxite for aluminium manufacture is the subject of a recent French patent. According to this method crude bauxite is powdered and dehydrated, and mixed while hot with boric acid or a borate, preferably borax (about 8%), and a quantity of carbon sufficient for the reduction of the iron and silicon contained in the bauxite. The mixture is fused in an electric furnace, the iron and silicon being reduced and forming compounds with borax, while the alumina is merely melted. The fused oxide is then run into a second furnace, or into another part of the first furnace, where it is reduced to alumina as usual.

Cement Engineering.—The department of Geology and Mining of the University of Arkansas, at Fayetteville, Arkansas, will offer next fall a four years' course for the degree of Bachelor of Science in Cement Engineering. Besides general engineering and geology, special work extending over two years will be given in the geology, occurrence, examination, and testing of cement materials and in the designing and operation of cement plants. In addition to the nearness of well-equipped plants in the Kansas gas district, the University is especially well situated for this work, since in the immediate vicinity of Fayetteville are well-exposed outcrops of limestone and shale, suitable for making portland cement. Students will be expected to sample these as thoroughly as possible and to make all necessary analyses in the chemical laboratory, and finally to prepare an outline design of a cement plant to utilize one of the more valuable deposits. At least two

*Decrease.

A paint which will indicate excessive heat in machine parts has recently been put on the market. The normal color is red, but when the painted part becomes heated it turns black, the red appearing again when the temperature falls. The paint is said to be made by mixing mercuric iodide and cupric iodide with distilled water in proportions which vary with the temperature which it may be desired to indicate.
The herein described sulphide ore smelting process consisting in the separation of the sulphur from the fused ores in the space or zone of the furnace below the fusion zone, by bringing the ore matte in contact with the carbon of the coke, out of contact with the air-blast, whereby the sulphur is removed in the form of sulphide of carbon, leaving the lead, gold, and silver in the metallic state and the copper as matte, substantially as described.

PROCESS OF TREATING ORE.—No. 895,196. James H. Reid, Cornwall, Ontario, Canada.

The herein described process of treating ore, which consists in passing the ore in a continuous stream through a number of electric arcs, introducing reagents while under the action of the said arcs, independently and withdrawing separately, the volatile products freed by each arc and independently treating the different volatile products after withdrawal.

ORE-CRUSHING MACHINE.—No. 893,540. Frederick B. Pettengill, Burbank, California.

In an ore-crushing machine, the combination of a non-rotating bottom track frame; a track on said frame; an upper track frame; a track on the under side of said upper track frame; crushing rolls between said tracks; a hollow vertical shaft secured to said bottom frame and passing upward therethrough, the upper end of said shaft having annular grooves therein; a spring frame surrounding the upper portions of said hollow vertical shaft and having annular lugs projecting into the annular grooves of said vertical shaft; a plurality of springs between said upper track frame and said spring frame; means secured to said spring frame for varying the tension of said springs; draft connections between said spring frame and said upper track frame; and means to rotate said spring frame.

In an apparatus for separating and amalgamating metals, a hollow, vertically journaled, substantially cylindrical and revoluble barrel or chamber with annular horizontal grooves in its inner surface to retain mercury by centrifugal force, vertical partitions fitting said grooves, an upwardly convergent hood fixed to the top of the barrel, with an open top, said hood having interior horizontal, annular grooves, a cone fixed to and revoluble with the cylinder shaft, said cone having a less angle than the hood, radial vanes fixed to the cone with their outer edges in close proximity to the interior of the hood, a source of supply at the top of the hood, and a receiver and discharge beneath the apparatus.

PULP-CLASSIFIER.—No. 895,092. Alfred G. Kirby, Goldfield, Nevada.

A classifier having in combination a casing provided with convergent sides, a narrow hopper at the bottom of said casing and communicating therewith, a sorting column forming a continuation of the bottom of the hopper, a wedge-shaped deflector in the casing having its sides substantially parallel with the inner sides of the casing and separated from the latter to form a sinuous passage for the pulp undergoing classification, and a water supply passing through the deflector and hopper into the sorting column.

An ore-concentrator comprising an endless traveling apron inclined upward in the direction of its motion, means for spreading ore on the apron, and means for discharging a transverse sheet of water onto the belt at regular intervals in the direction of movement of the belt, and in front of the spreading means.
Motor-Driven Cable Reel.

At the Lackawanna colliery of the Temple Iron Co., Olyphant, Pa., has recently been installed, by the General Electric Co., on a 6½-ton 'gathering-locomotive,' a motor-driven reel. This appliance exemplifies the latest development in gathering-locomotives, and is a distinct advance over the former methods of reel-drive wherein the reel is driven by means of chain and sprocket from the locomotive axle or armature shaft. In this new method the reel is driven by a small series-wound vertical motor, the frame of which forms a support for the reel proper, which, in common with all General Electric reeds, rotates in a horizontal plane on top of the locomotive. Double reduction-gearing is used, the lower end of the armature shaft carrying a pinion which engages with a gear, mounted on a vertical shaft, provided with a special oilless bearing supported by a cast housing on the motor frame. The upper end of this intermediate shaft carries a pinion which engages in a solid plate-gear onto which the reel disc is bolted. Ball-bearings are used throughout, both for upper and lower armature-shaft bearings and also for the reel, ball races being cut in the top of the motor-frame and on the under side of the reel-gear-plate. The whole mechanism is simple and compact, and consists of few parts, none of which are subject to hard wear. Renewals are consequently infrequent.

The motor is connected directly across the line with a resistance permanently in series in the circuit for preventing excessive flow of current. This circuit is controlled by a small single-pole switch, which may be opened when the locomotive is taking current from the trolley-pole and when the reel is not in use. The capacity of the motor is such that it may be stalled on the line indefinitely without overheating. The action of this series-motor is analogous to a spiral spring of infinite length and constant torque. With the locomotive standing still the motor will draw the cable taut, and exert a steady tension on it. When the locomotive moves forward and slackens the cable, the motor instantly starts rotating and reeves in the cable. Its tendency at all times is to produce a peripheral speed at the rim of the reel that is higher than the linear speed of the locomotive, so that there is a constant tension on the cable which insures its being wound compactly. When the locomotive changes direction, and unreeves the cable, the motor becomes a series generator, and has sufficient counter-torque to produce a tension on the cable that insures its paying out evenly along the road-bed. The braking-effect of this counter-torque is also sufficient to bring the reel to a stop the instant the locomotive stops.

This reel was installed some five months ago and has been in highly successful operation ever since. Its action is practically instantaneous, and the absence of shifting gears and other auxiliary apparatus renders it popular with the motormen. Beyond applying a little grease occasionally to the bearings, no other attention is required. The fact that the reel-drive is independent of any movement of the locomotive parts is an important feature of its operation. When, as frequently happens with the locomotive running down a heavy grade, the brake is applied, and the wheels are stationary, there is no danger of running over the cable. With former methods of axle or armature-shaft drive, any skidding of the wheels of course stops the reel-rotation, resulting almost invariably in cutting the cable. A rather interesting feature of the adaptability of the motor-driven reel is illustrated by the manner in which it is now being operated by the Temple Iron Co. They have a portion of their workings in which no trolley-wire has as yet been strung, but a feed-wire supplying power to another part of the mine runs along the roof. A point on this feed-wire is bored and the cable hooked thereon. The locomotive then runs ahead and stops when the entire 600 ft. of cable is reeled up. The cable is then unhooked, and a short jumper-wire connected to the feed-wire at the point where the locomotive has stopped. The reel-motor is then thrown into circuit, and when all the cable has been reeled in, it is again hooked to the feed-wire at this point, and the locomotive proceeds for another 600 ft., and so on indefinitely.

Pacific Coast Borax Co.'s $500 Prize.

A committee consisting of Iakobives, Roeber, and Backlund, appointed to draw up the regulations governing the competition for the award of the Pacific Coast Borax Co.'s prize of $500, submitted the following report: The sum of $500 has been paid to The American Electrochemical Society, and deposited in trust, as a research fund, to be awarded as a prize, under the following conditions: The Pacific Coast Borax Co. desires to awaken an interest in research work and experiments which may tend to solve or improve on commercial methods of facturing ferro-boron, by a direct process from colemanite. It is essential that the process should be sufficiently economical and suitable to be applied on a large scale, so that the finished product may be available for commercial purposes. Commercial ferro-boron, as now made, contains 20% or more of boron, less than 3% of carbon, and sulphur and phosphorus are practically absent. The prize has been deposited with The American Electrochemical Society, with the request that the board of directors award the same for the best practical solution of the problem, under reasonable conditions, to be decided upon by the Board of Directors. In accordance with the above, competitors for the prize are notified that they must comply with the following conditions:

1. The treatise on the subject must be in typewritten form and accompanied by a sample produced by the process described.

2. The competition for the prize is open to any one and is not restricted to members of the society. The treatise on the subject must be enclosed in a plain, sealed envelope, not bearing the author's name, but identified by a pseudonym. The outside of the envelope, containing the treatise, must be labeled with the pseudonym, and with it should be sent another plain sealed envelope, also labeled with the same pseudonym, which should contain inside the envelope, the name and address of the competitor. Both these envelopes should be sent to Prof. Morris Loeb, 273 Madison Avenue, New York City.

3. All papers competing for the prize must be in the hands of Prof. Loeb before October 1, 1909. Prof. Loeb shall retain the small sealed envelope, containing the address of the competitor and forward the large envelope containing the treatise, as well as the sample of the product, both merely labeled with the pseudonym, under cover, to the secretary of the American Electrochemical Society, to be submitted to the Board of Directors, who will award the prize as heretofore. In addition, the Board can act with entire impartiality and the paper shall be judged on its own merits, so that the author's standing can have no influence whatever on the decision. The competitors for the prize forfeit none of their property rights in the process submitted.

4. As soon as the Board of Directors has agreed upon the best treatise, it will request from Prof. Loeb the address of the author thereof, who will then be required to demonstrate his process, before the prize will be finally awarded.

5. The Pacific Coast Borax Co., 100 William Street, New York City, has offered to supply any one who desires to compete for the prize seriously, with all the crude colominate that the parties making the experiment may require, provided that the request for this colominate be accompanied by a letter signed by one member of the
Board of Directors of The American Electrochemical Society, endorsing the application for the material. This condition is merely made so as to furnish the material only to those who may have the proper qualifications to experiment intelligently and with some chance of success.

Copper Production in 1907.

The smelter production of copper in the United States in 1907, according to the United States Geological Survey, was 865,896,491 lb. From the record-figures of 1906 this is a decrease of 48,309,191 lb., or 5.5%, the largest actual decrease ever recorded, and the largest relative decrease since the American copper industry became important. This is the first time since 1901 that the annual production has been smaller than that of the preceding year, and the first time since 1872 that it has been smaller than that of the second year preceding. The total given above is made up of the fine copper content of blister produced, and of the smelter output of ingot and anode copper from Michigan. Of this quantity, approximately 16,075,048 lb. in blister were produced in foreign smelters from domestic materials. In addition to the domestic materials handled, smelters in this country turned out as blister 64,145,648 lb. from foreign ore, concentrate, and matte. Domestic blister containing 42,350,943 lb. was exported unrefined, while blister from foreign sources, containing approximately 183,580,322 lb. fine copper, was imported for refining in this country.

The greatest decreases in smelter output are shown by the returns from three States that rank highest. Montana's production, which was 294,701,552 lb. in 1906, was but 224,363,789 lb. in 1907, and the State yielded first place to its rival, Arizona, whose production, however, showed a decrease of nearly 6,000,000 lb., from 262,566,103 lb. in 1906 to 256,778,437 lb. in 1907. Michigan still holds third place, with its production decreased from 229,656,790 lb. in 1906 to 219,181,503 lb. in 1907. Decreased production is also shown by the returns from Alaska, Oregon, Washington, and North Carolina.

Many of the other copper-producing States showed substantial gains. The output of Utah, the fourth State in point of production, was nearly 15,000,000 lb. in excess of that of 1906, the figures being 66,418,570 lb. in 1907 as against 51,399,119 lb. in the preceding year. The production of California increased from 28,153,302 lb. in 1906 to 33,656,602 lb. in 1907; that of Colorado from 7,427,353 lb. in 1906 to 13,998,496 lb. in 1907; that of New Mexico from 7,999,342 lb. in 1906 to 10,140,140 lb. in 1907; and that of Idaho from 5,578,046 lb. in 1906 to 9,707,289 lb. in 1907. Nevada and Vermont also showed productive gains.

The production in 1907 of refined new copper of domestic origin was 784,371,247 lb., a decrease of 103,410,960 lb., or 13.2%, from the production of 1906. The total output of refined copper, exclusive of domestic scrap, by domestic refineries in 1907 was 1,032,516,247 lb. In addition to this production of refined copper 25,129,617 lb. were recovered during the year by the regular copper-refining companies of the country from domestic scrap, drosses, and so forth, and from these the addition made to all the known stocks of refined copper produced in this country has been included. These secondary materials indicate that 35,355,966 lb. of refined copper were cast by re-refiners, and in alloys. The copper produced from secondary sources in 1907 was therefore somewhat in excess of 60,000,000 lb., or more than 7.5% of the year's production of refined new copper.

Returns from all the Lake and electrolytic refineries are practically complete, and show the following stocks of refined copper on hand at the beginning and end of the year:

<table>
<thead>
<tr>
<th>Year</th>
<th>Pounds</th>
</tr>
</thead>
<tbody>
<tr>
<td>January 1</td>
<td>125,745,796</td>
</tr>
<tr>
<td>January 1</td>
<td>46,497,181</td>
</tr>
</tbody>
</table>

Increase during 1907...... 79,248,615

Undesired sales are almost entirely excluded from these figures, and stocks carried by consumers and brokers have not been estimated. In addition to these stocks of refined copper there were at the smelters, in transit to the refineries, and at the refiners, blister copper and material in process of refining to the amount of 135,310,239 lb. on January 1, 1907, and 175,234,659 lb. on January 1, 1906.

The apparent consumption of refined new copper in the United States in 1907 was about 485,000,000 lb., as compared to 685,000,000 lb. in 1906, and it is probable that in addition most or all of the 60,000,000 lb. of re-worked copper was consumed.

The figures given above are compiled from the exact records of all but one known producing company. A comprehensive report on the copper industry in 1907 is in preparation and will be published by the Geological Survey as an advance chapter from 'Mineral Resources of the United States, Calendar Year 1907.'

Instructions for Resuscitating Persons Suffering From Electric Shock.

In view of the increasing use of electricity in Mexico, G. & O. Braniff & Co., who are the general representatives in that country for the Westinghouse Electric & Manufacturing Co., of Pittsburg, Pa., are distributing among their customers large illustrated placards, upon which are printed Dr. T. Goellet's instructions for resuscitating persons who have suffered an electric shock. These placards are printed in Spanish and English, and are intended to be placed in generating or sub-stations, or wherever high-voltage electricity is employed. A thorough understanding of these instructions, and a careful observance of them at the time of accident may be the means of saving many lives. Recently a case occurred at a mining property in Mexico, in which a man having received a heavy charge from a $3,000-volt transmission circuit, was brought back to consciousness and ultimate recovery after more than two hours tireless application of these rules, which tends to confirm the belief that few cases of electric shock are necessarily fatal, unless the victim dies later from the effect of burns. These instruction cards G. & O. Braniff & Co. will furnish upon application, to parties in Mexico who are users of electricity.

Books Received.

The growth of cement construction is so great that an increasing number of books are issuing from the press to meet the demands for practical users. The present volume is essentially a handbook, giving the details of everyday work: specifications and testing of cements, the proportioning of materials for concrete, the making of mortar, forms and centring, laying out work, construction of sidewalks, curbs, coping, the making of cement blocks, the use of lathing and furring, making and applying plaster, and so forth. It is brief and practical, and will be useful as a ready reference work for the man in charge of construction.

An excellent review in brief of the formation of coal is given in this treatise, and the discussion of fossils as zonal indices is most useful, accompanied as it is with ample illustrations. Methods of study of both exposed and concealed coalfields constitute two suggestive chapters. As for the rest, the author's outlook is too wide to be of much service in details. It shows where, and how big, and how related geologically, are the important coalfields of the world, and thus presents a review valuable as a sort of "round-up."

Publications Received.

ON ANOTHER PAGE we publish a detailed description of dredging operations on the Yukon from information gathered on the spot. The article represents an earnest effort to get at the facts at first hand, and will tend to contradict some of the statements made in the columns of The Engineering and Mining Journal. We may state, in view of the destructive criticism which has been directed against dredging in the Yukon, and against the engineers of the Yukon Gold Company in particular, that we are frankly in sympathy with the men who are battling against natural difficulties, and who are overcoming them by technical skill. The work of the engineer must be looked at apart from the scheming of the financier, and the successes won should not be obscured by prejudice created by promoters' abuses of the facts ascertained by those in charge of solving the problems which would lead to success on a rational capitalization of the enterprise. The man who tries to conquer difficulties is progressive, at least; those who do not contribute to the solution of the problem and assert it to be insoluble are merely reactionary. It is obvious that the giving of support to optimistic schemes and the condemnation of conservative criticism is not the necessary corollary to such views as we express. Fair criticism is useful and ought to be more welcome to a reasonable man than unintelligent complacency. We hold that the engineers of the Yukon Gold Company are of such professional standing as to be entitled to an opportunity to show what they can do, and that their work at Dawson is not to be confused with the antics of frenzied financiers at New York. We wish a complete economic success to the technical men in the North and we hope that they will not be handicapped by the exigencies of finance. Nature is on the side of the engineer who knows how to obtain her aid.

AGITATION for stringent regulations to protect operatives in and around mines has become a feature of the political campaign this year in Idaho. One party proposes to enlarge the powers of mine inspectors, giving them summary jurisdiction in criminal proceedings against mine-owners for failure to comply with requirements which these officials may impose at their pleasure. On the other hand, lack of uniformity in the requirements made by different States introduces the peril of confusion. Even in so important a matter as hoisting-signals wide variations are found. Mine regulations, like those pertaining to the railroad world, should be the same everywhere. But it is easy to over-regulate. The tendency is always to burden mining operations with petty requirements, often impossible of strict
The Lure of Buried Treasure.

The reason why the moralists have had to preach the virtue of patient labor so persistently is, of course, that patient labor is opposed to a strong romantic spirit in man which civilization has for ages been trying in vain to eradicate. Civilization is a leveller. It is a mechanism; it abhors the loose wheel or the unmatched gear. But the romantic spirit will break loose ever and anon, and men will indulge in a secret longing for contact with the forbidden romance of the wild old days. At least we think of the old days as being wilder and more romantic than our own, though perhaps they seemed quite hum-drum to all save the few who figured on the swash-buckling skirmish-line with or against the pirates and the outlaws. Our own peculiar forms of romance will probably appear quite interesting to those who may behold them in far perspective from the future, and the evil of them will be plainer than to us. And yet human nature will not change as much as human customs. There will always be a turning back; perhaps someone will revive the brilliant game of the endless chain of bond-issue and stock-purchase to control the traffic of a continent. So far as we are concerned, our return to a romantic past is to such crude and gross materialistic things as buried treasure, and association with survivors of piratical adventure, which shows by contrast how much more delicate and refined is the structure of modern romantic practice.

The treasure-hunter is no myth of the Sunday newspapers. The sanest plodder in commercial life is liable to be attacked with the fever. It broke out in San Francisco several years ago, when an expedition was financed to seek the Cocos Island treasure. The schooner Herman was purchased, equipped, and manned, and the company sailed for the South Seas under command of Captain James Brown, alias Brawn, said to be a self-confessed buccaneer, who helped capture treasure-ships bound from Australia to England in the days when the Indian ocean was not as safe as it is today. The expedition was one of continuous excitement and ultimate disaster. The instincts of the pirate—bluster, suspicion, cowardice, treachery, cruelty—all came out in strong relief.

The story was told by one of the treasure-hunters in a book entitled, 'Our Search for the Missing Millions,' published in 1904. It would hardly be worth recalling, except as a reminder of a lost opportunity for some melodramatic playwright to win reputation, were it not that the irrepressible Brown has stirred the enthusiasm of some calculating New Englanders who have organized a company under the laws of Massachusetts for a second effort to obtain the long-lost treasure. At the same time a rival party is in the field. The Messrs. Robinson of Streatham, England, in company with Lord Fitz Williams, have obtained a concession to Cocos island from the Costa Rican Government, to search for buried treasure, coupled with a saving privilege to explore for minerals. Myth and conflicting tradition alternately favor the opposite theories on which the two expeditions have been undertaken. Captain Brown avers that he helped remove the stuff from its ancient resting place to an uncharted island in the vicinity of Samot. Part of the treasure being kept for immediate use led to a series of unmentionable barbarities which left Captain Brown in possession. Others affirm that the treasure was never taken away.

The story has some foundation in fact. When the royalist adherents in Peru had taken final refuge in Callao from the revolutionists, in 1820, they are reported to have despatched a vessel with treasure and other valuables for friendly shores. The crew mutinied, and buried the coin, plate, and jewels on Cocos island, which is a solitary peak rising 2800 feet out of the ocean about five hundred miles west of Panama. While the story up to this point may be true, it is evident that too many knew the secret, and that the treasure has long ago passed into general circulation. Meanwhile Captain Brown has given refreshing proof that the blood of New England is not so frozen but that it may still respond to the thrill of the romantic tales of jolly buccaneers.

Fee-Simple Tenure of Mining Property.

The question is raised by a correspondent, whose letter we publish in this issue, whether demonstrable superiority over the leasehold system inheres in the American law which grants absolute title to mining land. This leads to something more than a mere academic discussion. The creation of National Forest Reserves, as part of a broad policy for the preservation of natural resources, has re-opened questions supposedly stilled forever in statutes and decisions which had apparently crystallized certain principles into our organic law. The re-appearance of the Government as landlord would not have been seriously mentioned a few years ago. Changing needs, however, dissipate reverence for conservative restraints, and when the mining law refuses to harmonize with forest regulations, and subjects the plain intent of the forests to peril, the essential desirability of fee-simple ownership may require further defense. The superiority of that principle has not been taken for granted, and there exist many advocates of a different basis of right applicable to mining claims on forest reserves. Nevertheless, we
do believe the individualistic spirit in America to be so strong that there will occur no turning back from the ascending course of development which has marked the growth of our institutions. We affirm this in spite of recent tendencies toward centralization which have won applause for the administration of President Roosevelt.

A leading characteristic of the political evolution of the United States has been an accentuation of the rights of the individual, accompanied with elimination of those forms of governmental scrutiny and control which have always proved oppressive. The nearer government approaches the functions of a protector of private rights under laws that give no unequal opportunity, the more perfect it is. The phenomenal growth of this country has been due in large part to the exaltation of the rights and privileges of the individual, and among these the extension of the principle of ownership in fee-simple has been more thorough than in any other country in the world.

Our correspondent questions whether necessary advantage lies in such tenure of real estate. He limited the case to mining claims, but we put it thus broadly, for if it is not essential to the best development of the mining industry the argument for a leasehold system would apply with equal force to any real property whatsoever. The fact that five-sixths of the mining areas in the world are administered under the concession-principle indicates at once that the United States occupies a position in this matter apart from the customs of other nations. This means, then, that with the exception of copper the majority of the metallic wealth of the world is produced under a mine-tenure which is not secured by absolute indefeasible title. Evidently capital has not been sensitive to the possibility of forfeiture involved in such a system, hence it is most reasonable to inquire wherein lies the superiority of one system over the other? In the Transvaal, which led the world’s production of gold with $10,676,000 in 1907, the State retains the ownership of minerals, and exacts both ground-rent and a tax on the net output of the mines; but the country is not entirely open to the public. Several exclusive concessions covering large territories are in existence. Monopolistic privilege is one of the evils which readily creeps in under the principle of government ownership. This has also limited the advancement of several districts in Canada. Otherwise the Dominion is as open and fair as it can be under the concession-system, which in effect colors nearly all legislation concerning mines, despite a limited granting of fee-simple titles to certain mineral lands in a few of the Provinces. The abuses at Cobalt, stimulated by the greed suddenly developed in the face of possible extraordinary revenue, is a case in point. Where the principle of the concession, or the leasehold, prevails, instead of the fixed conception of the government as only a trustee for the public with regard to unimproved lands, to hold them until demanded in fee-simple by individuals, one can never tell what freaks in contravention of the liberty of the people may be displayed by the lawmakers. Liberty to develop and utilize the natural resources of a country without fear of having the fruit of one’s labor destroyed by withdrawal of lands from acquisition in the normal way as soon as they may be shown to possess value, even though such withdrawal be temporary, is an evil which can arise only where the ruling political theory is grounded in a past that had not risen to the highest conception of the rights of the individual.

In Egypt the granting of immense concessions has been the chief feature of the Government’s effort to develop the mineral industry. The governmental restrictions extend even to the transfer of mining property, requiring the consent of the Minister of Finance after presentation to him of the details of the transaction. The concession-system also prevails in India, where heavy royalties, amounting to 7½ per cent on the net profits, are collected from producers of gold and silver. Payment of heavy royalty is also exacted in the Malay Peninsula, accompanied with the requirement of continuous work. In Australia the system is that of short-term leaseholds, renewable to previous tenants, with the tenure dependent wholly on the punctual payment of the rent, and the continuous employment of a certain number of men underground. In Spain concessions are in perpetuity, subject to payment of annual imposts, failure to pay which causes forfeiture within fifteen days. Another inconvenience of the concession-theory, found in Spain, and to some extent appearing in many countries subject to these ancient customs, is that more than one concessionaire may have contemporaneous rights in different minerals on the same piece of ground.

The cases given reveal only a few of the difficulties proceeding from this system. They are difficulties derived from the false notions concerning individualistic rights on which the feudal system was founded. The penalties attached to non-payment of taxes are not comparable to the swift and irrevocable forfeiture which follows failure to pay rent or royalty. Fee-simple ownership accords rights which strike deep root into the soil. The severance of such an owner from his estate is not easy. Though he may have failed in all his obligations and have long abandoned the land, the title of a later claimant is clouded by that old possessory right until wiped out by a decision of a competent court. Nor so with the leasehold. Failure to pay erases the claimant as if he had never been, and the next man who steps on the ground, and complies with the regulations, is master. Here, at bottom, rests the great difference which gives such paramount advantage in point of security to a title in fee-simple. It is a title that protects the man, whereas under the concession-system the man must protect the title. We have a perfect example of the great contrast between the stability of possession under the two systems in the tenure of a mining claim before and after issuance of title in the United States. The least irregularity opens the way for the ‘claimjumper’ until the parchment comes from Washington with the great seal. Then the claim-pirates must needs seek other and easier galleons to loot and settle.
Personal.

J. B. Fleming is in San Francisco.

Howard D. Smith is in Amador County, California.

Evelyn W. Stenius is in Calaveras County, California.

T. J. Logan, of Waldo, Oregon, was in San Francisco last week.

J. M. Callow has returned to Salt Lake from a trip to Alaska.

Arthur W. Stevens has moved from Boise, Idaho, to Los Angeles.

L. D. Carter, of Oakland, California, has returned from New York.

H. Foster Rain, of Urbana, Illinois, was in San Francisco this week.

John B. Parish was in San Francisco last week and has gone to New York.

W. J. Mitchell has returned to Santa Eulalia, Mexico, from a visit to California.

H. V. Welsch is at Wallace, Idaho. He will return to Minneapolis on September 1.

R. H. Tolt, of Denver, is making an inspection of the Montezuma district, Colorado.

E. J. Moore, Colorado manager for the Mining and Scientific Press, is in San Francisco.

J. E. Sauer has been making an examination of the Camp Bird mine, in Curry county, Colorado.

W. L. Cook, of San Francisco, is at Atlanta, Idaho, where he will be on examination work for several weeks.

G. W. Winter is ore-buyer for the United States Mining & Smelting Co., stationed at Butte, Montana.

F. S. Shevell has been appointed manager for the Arizona Gold & Copper Hill Mining Co., Phoenix, Arizona.

J. V. N. Doan has returned to the Black Hills from a two-weeks’ visit to the Nelson, B. C., district on professional business.

H. A. Gues has been appointed manager for the Federal Lead Co., Flat River, Mo., which appointment will take effect October 15.

H. S. Washington, of New York, has sailed for South America, where he will spend several months in the gold-mining districts of Brazil.

Lucien Eaves, of Los Angeles, has gone to Mexico for an extended examination of the San Miguel group of mines, at San Miguel del Mequiltil, Zacatecas.

H. F. Lefevre has recently returned to Reno, Nevada, from a trip through Arizona, Mexico, Guatemala, and Salvador. He is now on an inspection trip to central Nevada.

Edward L. DeBoor has returned to New York, after an absence of several weeks at Mexico City. While there he underwent an operation for appendicitis, which was entirely successful.

Catalogues Received.

The Ernest Wiener Co., of New York, has recently issued an attractive folder calling attention to some of its specialties.

The Cleveland Pneumatic Tool Co., Cleveland, Ohio, has recently issued Bulletin No. 46, describing the No. 40 Cleveland stope-drill.

The Vulcan Iron Works, of San Francisco, has recently issued a new catalogue giving full information regarding ice making and ice-making plants.

The Powers & Mining Machinery Co., Cadathy, Wis., has recently issued Bulletins No. 27 and 28, describing respectively Huntington mills and crushing rolls.

The Joshua Hendy Iron Works, San Francisco, has recently issued Bulletin No. 111, on gravel elevators and water-lifters. The pamphlet is handsomely printed and illustrated and gives much valuable information, aside from the descriptions of apparatus.

THE CALIFORNIA DEBLOOM COMMISSION, having received applications to mine by hydraulic mining from Berkeley Placer Mining Co. in Berkeley Placer Mine, near Lowell Hill, Nevada county, California, for mining into Searles hollow creek, and from Cleveland Gold Mining Co. in Cleveland Mine, near Stockton, Sier county, California, draining into Rock creek, gives notice that a hearing to receive any protests will be held at No. 1728 fine St., San Francisco, California, September 15, 1908, at 1:30 p.m.
General Mining News.

ARIZONA.
GILA COUNTY.
A small force was put to work on the Keystone property last week, making roads and trails to facilitate the moving of machinery and supplies and grading sites for drilling rigs. It is proposed to prospect the ground by sinking a series of holes 600 ft. deep, about 200 ft. apart, with churn-drills.

MOHAVE COUNTY.
The Golden Gem mill, at Cerbat, was started up a few days ago on a 75-ton sample of ore from the Red Seal mine, which was acquired by the Company two years ago. Should this sample lot give good results it is the intention of the Company to work the mill on a large scale. At the Gem mine the Company is unwatering below the 300-ft. level and expects to be ready to commence sinking by next week. Everything above the 300-ft. level has been put in first-class shape.—A discovery of four feet of $102 gold ore on the sixth level of the McCracken mine, at Kingman, has caused considerable excitement because that property has always produced only silver-lead ore in the past. A reduction plant is one of the future improvements planned by this concern.

The old board of directors of the Redemption Copper Co., at Chloride, has been re-elected. A hoist has recently been installed and work on the mill is progressing rapidly.

SANTA CRUZ COUNTY.
An arsstra is being built on claims near Patagonia owned by C. B. Wilson, J. W. Morris, and A. E. Moody. The ore to be treated is a black chider easily ground to powder, and carries considerable fine gold. The vein is two feet wide at the surface, but at the bottom of a 35-ft. shaft has a width of five feet. On another claim there is a two-foot vein of quartz which assays $29 gold, with some silver.

YAVAPAI COUNTY.
(Special Correspondence).—The Mildred Gold Mining Co., has recently installed a new steam hoist at its shaft on Rich hill, in the Weaver district, and will push developments. This property has been worked since 1855, and no small amount of ore has been shipped by Dan Gens and his father, from whom the present owners purchased the property.—John R. McDonald has uncovered a 18-in. vein in the Slite Creek country, between the Jersey Lily and the Blue Dick mines, which assays $25 per ton gold and 2% copper. A shaft will be sunk.

Phoenix, August 24.

The 10-stamp mill of the Elliot Com. Mines Co., at Chaparral, is running steadily, and regular shipments of bullion and concentrate are being made. The present rate of concentrate shipment is two cars per month. Sinking will soon be resumed in the 400-ft. shaft, and a 10-drill air-compressor will be installed. It is the intention next fall to replace the present 10-stamp mill with one of 40 stamps weighing 1900 lb. each.—The Green Mountain group of mines, in Copper Creek district, 10 miles south of Prescott, has been sold to a syndicate composed mainly of New York men. The property has a shaft 230 ft. deep, and several hundred feet of drifts, in one of which is a large body of copper.

CALIFORNIA.
AMADOR COUNTY.
The South Eureka has commenced the erection of a cable tramway from the mine to the Central Eureka mill. The South Eureka has more ore than can he handled at its own 20-stamp mill, so it is proposed to use 20 stamps of the Central Eureka until that mine has reached a stage of development requiring its full milling capacity.

Butte County.
The city of Oroville has enjoined the Indiana Gold Dredging Co. from enlarging or continuing the pile of tailing at its dredge on Feather river. It is claimed by the city that the dredging company has reduced the width of the channel over two-thirds, and thereby endangered the property of the city and of its inhabitants. As the result the dredge has stopped work.

ELDORADO COUNTY.
A company of Los Angeles men has purchased the Joe Delwisch and the Jimny Breedlove mines, on Otter Creek hill, about four miles north of Georgetown, from L. H. Fowler, of Roseville. W. H. Hartvig is at the property in the interests of the new owners, and will start development work at once.

NEVADA COUNTY.
(Special Correspondence).—The rich orebody opened up in the 200 and 300-ft. levels at the Kenosha has been intersected by a drift on the 400-ft. level. The pay-shoot has widened to 12 in. and assays run from $100 upward. The shaft is down below 400 ft. and is being sunk steadily. More men will be added to the force within a short time.

—A company of local people have bonded the old Hill mine, in the heart of Grass Valley, and will thoroughly explore the property. When last operated a good vein of milling ore was opened up.—The company which recently took a bond on the Normandie is rapidly completing arrangements for the working of the mine on a large scale.

The Graystone mine, in the northern part of the county, has been purchased by J. S. McKiag, of Pittsburgh, and Johnston Slingshaff, of Baltimore. The shaft will be sunk to greater depth and considerable development work carried on. George Hegarty is superintendent. The same men have taken a bond on the Snow Point mine and propose to work it extensively.—Two new transformers are being placed at the Alaska mine, to replace those recently destroyed by fire. Operations at the mine will be resumed within a week.—Samuel Colt has arrived to take charge of the Lecompton and Oustinoham mines. The former is being rapidly watered, and experts are sampling the Oustomah ore.—A. M. Gilbert, of Santa Barbara, has bonded the Dillion, Dower, and Boston properties, in the Graniteville district. Active work is planned.—Owing to the shortage of water, only five stamps are running at the Yuba mine.—The same company is working one shaft at the Grey Eagle mine. The report that the Eagle Bird mine has been re-opened is erroneous.

Grass Valley, August 24.

SHASTA COUNTY.
The Greenhorn copper mine, in the French Gulch mining district, has again been bonded by the Bully Hill Copper M. & S. Co. This Company did about $10,000 worth of development work on the mine, commencing in the fall of 1905 and ceasing about the time of the paucie last year. J. W. Heath, employed at the Mammoth mine, is one of the owners of the Greenhorn property.

SISKIYOU COUNTY.
One of the big transformers at the Alaska mine has again burned out, and things will be at a standstill for ten days, until it is replaced.—F. P. Reddy has now 11 men at work on the Reese ravine property. Andy Johnson, of Deadwood, and Scott Bros., of Poker Flat, have taken a contract to whip-saw 10,000 ft. of lumber, which will be used in building the mill, boarding-house, and other buildings.—The contractors on the lower adit of the Tighten, at Alleghany, threw up their contract last week on account of the hard rock, claiming that they were hardly coming out even. Two shifts were, however, put to work Monday morning by H. L. Johnson, and the work will be completed by day’s pay.

L. R. Fulcher is making an examination of the Las- siat mine, in the interests of DeGolia & Atkins, of San Francisco, who have a bond on the property.

SEOKIYOU COUNTY.
C. P. Elmore, who owns two groups of claims on the west fork of Big Humbug, recently leased a part of his holdings to Kiernan Bros., of Yreka. A twin-tub arsstra is being built near the property, in which will be treated the ore from both the Kiernan lease and Mr. Elmore’s operations.—A cinnamonic prospect of some promise is owned.
by A. M. Cowgill on the west fork of Beaver creek, near the Garretson dike. The property comprises three claims, the longer of which is the dike and the contiguous schist. The dike is composed of a network of seams, gashes, and fissures, which all carry the quicksilver-bearing ores, that occur largely as a sulphide or crystalline dike, more or less pure, or finely disseminated throughout with a fine-grained sugary quartz. The ground is crossed by a ditch, the water from which Mr. Cowgill is using in an effort to cross-cut the dike and sluice away the surface soil, to enable him to follow any one of the numerous seams to some source or point of origin.

TRINITY COUNTY.

A strike of rich ore was made in the Brown Bear mine, near Deadwood, last week by E. E. Paulsen and associates. The property has been idle for some time, and the owners had been working only a short time when the find was made. It is said the vein is four feet wide, and that samples assayed as high as $500, while the whole width will average $100.

COLORADO.

CLEAR CREEK COUNTY.

(Special Correspondence.)—The bond of $10,000 upon the Ramidell group of six claims, on Lincoln Mtn., was paid this week. The Ramidell G. M. & M. Co. has been reorganized and it is understood that funds have been provided for extensive development. The Market adit is to be advanced to the intersection with the Golden Jack vein, which is known to come to a cross-cut of the entrance. A streak of high-grade silver-lead ore is being followed for 6 to 18 in. wide. These losses control a block of ground 200 ft. deep by 100 ft. long.—M. J. Riley, owning a group of 21 claims on Democrat Mtn., is making ready to start extensive development. During the past week a number of Denver capitalists have been in camp, and it has been decided to start an adit. This property is on the eastern side of the hill and is surrounded by much well-known producers as the Sunburst, Astor, and Poly Star.—A. M. Robert, owner of the Sunburst Extension, has resumed work. The cross-cut is being driven forward and another vein will be reached within 25 ft. In the Sunburst Extension vein, which was assayed some weeks ago, a streak of high-grade ore is showing that is from 4 to 6 in. wide, but owing to the shallow depth secured, no driving has been done.—W. T. Bushman, of Buffalo, N. Y., has been in camp during the past ten days. Mr. Bushman has been appointed trustee, for the holdings of the Magnet M. & M. Co., operating through the Duric adit. A company is now in the course of organization to be known as the Buffalo M. & T. Co., and Mr. Bushman states that ample funds will be forthcoming for future operations. A force of 16 men in two shifts is now employed, but more will be on hand in short time. Operations are being centred in stoping on the Magnet vein, cut 2400 ft. from the entrance of the adit. A streak of smelting ore is exposed for 150 ft. which is from 1 to 4 ft. wide, the value of which varies from $40 to $175 per ton in gold, silver, lead, and copper. From what can be learned of the plans of the new Company, the adit is to be advanced for several hundred feet. The Buffalo M. & T. Co. is leasing on the Grant level of the Sunburst, will start shipments of high-grade ore the coming week. For some time past work has been under way in the driving of the west drift, the ground having been opened for 50 ft. From the last shipment returns of 420 oz. in silver per day were received, and now headway is being made in the advance of the Burns-Noe adit on Chicago creek. In the raise being carried on the Black Lion vein the streak of ore is gaining in size, now being 10 in. wide. Driving is to be started to the eastward for the proving of the extent of the discovery.—Heavy shipments of ore are being made from the Breckenridge on M. & M. Co. holdings. This property will eventually be operated through the McClendon adit, a contract to that effect having been entered into some months ago. The adit is now nearing the Pittsburg vein, and as soon as the objective is reached driving will be started.—The aerial tramway running from the sixth level of the Mineral Chief mine is now destined to use the Sunburst ore to the Linn Co. mill. The machinery is doing excellent work and shipments of concentrate have been started.

Georgetown, August 22.

LAKE COUNTY.

Recently Pugil, Kim, and associates obtained a lease on a portion of the Alps consolidation of claims in South Evans, and they have placed a hoist on what is known as the Shinn or Ward shaft on the Columbus claim. The shaft was sunk eleven or twelve years ago to a depth of more than 160 ft. without penetrating the lime. A streak of ore was found and some shipments made from it. The ore was a heavy galena with some gold and silver.—The Dempsey tunnel, near the London, has been leased to Denver parties represented by F. J. McNair, and men and supplies are now on the ground to push the work vigorously and systematically.—At a depth of 70 ft. a streak of tellurium has been opened in the Margaret mine, near Granite. This contains a heavy deposit of gold. Shipments have been made on the Leadville smelter.—It is likely that arrangements will soon be made for the extensive operation of the old Kankakee property, in the Big English gulch. During the past year some high-grade ore was taken from this property, but it has been worked only in a small way. There is a long adit on the Kankakee, through which the country is drained.—It is thought that the Ilex No. 4 shaft, which has been closed since the first of the month for repairs, will be ready for operations before September 1. The re-reaming of the shaft is progressing rapidly, and the other improvements which were planned will take less time to complete than was figured on.

SAN JUAN COUNTY.

The Danville Leasing Co., composed of people from Danville, Ill., has been incorporated to work a lease on the Shanandoah property through the Triby adit. The company has been at work some time and has started drifts in both ways, and has turned up some very good silver ore.—George Hider, of Tchotchkin, has been put in charge of the Newport property, on Engineer Mtn., and now has a force of eight men doing development work.—It is believed that the recent tests which the Contention mill made on the Champion are entirely satisfactory, and that the Ross Co. will build a mill at once. T. C. Woodward, who had charge of the tests, has gone to Pittsburg to confer with the officers of the Company, and it is stated he will return to Silverton early in September and start actual construction.—The recently organized Iowa-Tiger Leasing Co. has started a small force of men cleaning up the tramway and will begin mining operations as soon as supplies can be taken to the property.

SUMMIT COUNTY.

In the eastern end of the county, between the north and middle forks of Swan river, a new mining camp, called Goldsboro, has been established. The chief operators are a mill. —The Snyder placer, on the Swan, near Breckenridge, resumed operations last week and under a temporary agreement with the Colorado Gold Dredging Co., pending the settlement by the courts of the injunction secured by the latter, the agreement holds for four years.

TELLER COUNTY.

The C. B. Wheeler G. M. & L. Co. is to be incorporated to work the Alhambra property, on the west slope of Squaw Mtn., near Cripple Creek. One of the members of the Company claims to have found a shoot eight years ago which assayed as high as $39,000 per ton, and it is this vein which the new Company will explore.—The Roosevelt deep.
drainage tunnel is now in a little over 2000 ft., and satisfactory progress is still being made.—The Birdsell Lea-
sing Co., operating the properties of the old Rittenhouse G. M. Co., the White Elephant, Happy Day, and Fraction No. 1, on Gold hill, made its initial shipment last week. The leasing company is breaking ore on three levels, the sec-
ond, fourth, and sixth, from a vein from four to six feet wide, and is using machine-drills. The ore is of mill-
ging grade, and is estimated to be worth from $10 to $15.—E. F. Woods and associates have taken over the lease on the Maloney shaft of the Isabella Mines Co., formerly held by Wilson Bros. A shipment will soon be made.

IDAHO.

SHOSHONE COUNTY.

(Special Correspondence.)—The Amador mine, near the Montana-Idaho divide, concerning which there has been so many scandal, is to be re-opened and a company formed to merge the interests of the Amador Gold & Copper M. & M. Co., the Amador Railroad Co., and the Amador Smelting Co. into one concern, with a single set of officers. The reports to the effect that this property was worthless did per-
haps more harm to the district than anything else within recent times. Wilbur Gruss, treasurer for the re-organized company, has been in the district for several days past, and has secured the cooperation of practically all the local stockholders. A syndicate of these had already engaged John H. Nordquist, a mining engineer of this district, to make an examination of the property. His report was ent
erly favorable, and the syndicate has at the present time sold the property itself and repaired the railroad at his own cost, involving a sum of not less than $3000. It is calculated that there is enough ore in sight to run the smelter for at least six months. Every effort is being made to pay off the Com-
pany’s indebtedness of about $50,000, and local holders have been led to believe that the mine will be on a full shipping basis within the next twelve months. The personnel of the new management has not yet been decided upon, but the syndi-
cate of Wallace business men, headed by Forest D. Fra-
sler, has taken a two years’ lease of the property of the Josephine Copper Mining Co., near Stark, Mont., together with an option to purchase within two years from August 10. The lease stipulates that a force of men shall be kept continu-
ously at work on the property during all the life of the mine. The Company is to receive 40% of all smelter returns on the ore shipped. Already several large bodies of ore have been opened up and a considerable amount shipped. Development work has been carried on for more than thirty years.—A strike of 3 ft. of rich carbonate ore has been made on the property of the Coeur d’Alene Vulcan Mining Co., about two and a half miles west of Wallace, and adjoining the old Argentine mine. The ore carries some gray copper and native silver, and assays 45 to 50 oz. silver per ton.—The Amy property, on Pine creek, near Wardner, which has been held under bond by J. L. Safford, has been bonded by Mr. Safford to J. H. Kins-
ley of Spokane for an amount said to be in the neighbor-
hood of $200,000. The group consists of eight claims be-
tween the Corrigan and Wonder mines. Almost 2000 ft. of drilling have been done, and the ore has been extremely rich and payable.——A car of ore is about to be shipped from the property of the Swatkitka company, on Four Mile gulch. The vein on this property has been exposed for a distance of 250 ft., showing ore which assays all the way from 4 to 20% copper and carrying a pay-streak about 15 in. wide. It is ore from this stretch which will be shipped.—An assess-
ment of five mills per share has been levied on the stock of the Almada Mining Co., payable September 26 and de-
linquent 30 days after that date. The money raised will be used to carry on work on the property.—The recent strike on the property of the Great Western Mining Co., near Burke, has now widened out to about 24 ft. of good milling ore, at a depth from the surface of about 75 ft. Another adit is being driven to tap the vein farther to the east. T. H. Scott, the manager, has purchased silver with a capa-
city of 500 ft., and as soon as this has been installed a shaft will be sunk at a point near the approximate centre of the ore-shoot. During the progress of sinking, Mr. Scott will con-
tinue driving eastward to determine the length of the ore-
shoot.

Wallace, August 22.

KANSAS.

CHEROKEE COUNTY.

(Special Correspondence.)—The Wyandotte land south-
west of Galena has been opened to operations at a re-
duced royalty, and as a consequence a number of new leases have been taken. The ore is found from 55 to 108 ft. Only the western portion of the ground has been prospected, but the company states that there is enough ore in sight to supply the mill for several years. The Rockenback, Dilllon, Ramsay & Co.—Twenty acres north of Galena, developed by Ping & Robertson, have been leased by New York capi-
talists. Four drill-holes on the leases developed ore at 225 ft., and also at 299 ft. A 250-ton mill will be erected on each ten-acre tract, and a shaft begun by September 1.—An old shaft discovered under tailing and debris on the old Delta Mining land in the southwestern part of Galena has caused considerable interest. The shaft is very small, about 3 by 3 ft., and is a relic of the early mining days. Ore was bought from this shaft more than 25 years ago. John Franklin and associates own the lease and are in-
stalling machinery with which to operate through the old shaft.—The Herald Mining Co. has been closed down for several weeks while work has been rushed in bring the old mining shaft to the water deposit. The shaft will be sunk entirely through the orebody, which will then have a 76-ft. face. The vertical shaft will later be con-
ected to the incline. During the sinking of the shaft a large orebody was struck which gave good assays in lead. When the development work is completed the mill will be started.—A 200-ton mill is to be built on the Malard & Manton ground, at Peacock. Extensive drilling has been done, and an existing adit has exposed a rich zinc-blende orebody from 174 to 188 ft.—Three new mills are being erected in the vicinity of Baxter Springs. Wigginton & Milton are pushing the erection of the Lucile mill. The Good Luck will have a plant running by September 1, and a 150-ton mill is being built on the Chicago-Qupaw lease.

Wallace, August 22.

MISSOURI.

JASPER COUNTY.

(Special Correspondence.)—The greatest innovation in the district is the starting of a steam-shovel in the Ameri-
can Z. L. & So. Co.’s No. 2 shaft, as Prosperity. The ma-
chine has been in operation about five weeks and although not much of it has been the experimental stage, the op-
portunity is being taken to see if the work is economical. The machine is 10 ft. wide, and is driven by a 20-horsepower engine. The ore is dumped into a car at the face and carried to the shaft and piled on the mill lease. The machine is well developed with numerous drifts. Operations have been started by the new company.—Many prospectors are seeking shallow lead deposits on the land of the Center Creek Mining Co., encouraged by the lower royalty re-
quired by the land owners. The royalty has been reduced from 25% on zinc-blende and 40 to 50% on galena to 20% on both ores. Galena is often found at 30 ft. and a num-
ber of good strikes have been reported. The custom mill, which was burned last spring, has been re-built and is now
being operated by H. C. Gaston.—There is a great amount of activity in the mining region south of Joplin. At Springs City, the Argosy Mining Co. has undertaken a greater amount of development work. Two drifts have been run out from the shaft at 112 ft. toward two drill-holes 85 ft. away and the drifts penetrated rich ore so that the small mill is being taxed to care for the product.—The Company is preparing to remodel the mill, installing new machinery and increasing the capacity. A drill is at work prospecting the ground along the Chalk hood near the Summit. Two good drill strikes have recently been made on lease by Budd Robinson while prospecting two strips of ground aggregating 650 acres. The ore is found from 110 to 140 ft. and seems to be in an old water channel. The same formation was found in the Midnight mine, where the walls of an old water course were rich in ore.—The Diamond Jack mine, at Chitwood, is again under operation and two miles of ore have been worked. The 150-ton mill has been idle about three weeks, but a large force of men has now been put to work. The ore is being worked at 160 ft. and the deeper deposits will be developed later.

Joplin, August 22.

MONTANA.

LEWIS AND CLARK COUNTY.

(Special Correspondence.)—The Spring Hill mine is situated four miles south of Helena, in Orofino gulch. The holdings of the Spring Hill Co. adjoin the Whitlatch group, the latter being on the opposite slope of the ridge that separates Orofino from Grizzly gulch. The Whitlatch has not been operated during the past year, and its air-compressor, 260-ft. mill, and cyanide plant have been leased to the Spring Hill M. Co. The use of the compressor will be continued in the pipe-line was laid from the compressor-plant to the Spring Hill mine. The ore is hauled from the mine to the Whitlatch mill over a surface tramway, built in four sections. The first consists of a mile of level trackage; the second is an incline 600 ft. long, by which the cars of ore make an ascent of some 200 ft. to the top of the ridge, where they are discharged into bins; the third section consists of surface trackage from the bins to the crushing plant near the Whitlatch shaft; the fourth section is an incline, over which the crushed ore is conveyed to the stamp-mill in side-dump cars. The ore-zone of the Spring Hill is in granite, near the contact of the latter with limestone. It is opened by an adit which was driven 750 ft. along the lode, and two good ore faces are being worked following a vein of pyrrhotite which was partly in the line. In this work the object was solely to extract the pyrrhotite, required as a flux for a Butte smelter. When, within the last two years, the Spring Hill company, under the management of F. L. Sizer, got control of the property, cross-cuts were driven at regular intervals from the old adit into the granitic strata, and the ore faces were being worked follow the line-contact, demonstrating the existence of a mineralized zone on the granite side of the contact, ranging from 40 to 80 ft. wide. The gangue material is a silicified granite, carrying gold in the free state, and associated with iron pyrite. This zone strikes east and west, the north boundary being the line-contact; on the south side there appears to be no wall or definite boundary, as the mineralization gradually fades out into the granite. By extending drifts from one cross-cut to another, great bodies of ore are blocked out. A 190-ft. winze has been sunk from the main adit-level on the vein, and extensive driving and cross-cutting has been done from the station at the base of the winze. An air hoist operates a cage in this winze. The Company has 1½ miles on the strike of this zone. The mill, which is operated by electric power, crushes to 20-mesh and handles about three tons to the stamp per 24 hours. The larger part of the gold is recovered on the plates, the pyrites are taken up by Willey tables, and the tailing is passed through launders to the cyanide plant, where the sand and slime are parted by spitzkasten and Callow classifiers. The slimes is cyanided in agitation-tanks, and the sand in the regular leaching-vats, having Butters distributors for filling them. The precipitating is effected in zinc-boxes of the usual type. Mr. Sizer speaks of the possibility of the Spring Hill Co. extending a mill at the mine capable of milling from 590 to 700 tons per day.

Helena, August 22.

NEVADA.

EMERALDIA COUNTY.

The Hazel Goldfield Mining Co. has let a contract to J. M. Bench for additional depth in the Company's shaft on the Last Chance claim of the Laguna estate of the Goldfield Cons. Mines Co., namely from the 550 to the 550-ft. point. Mr. Bench has also been given a contract for lateral work on the 450-ft. level, where a promising stringer was found while sinking the shaft. The Goldfield American has resumed work. The shaft has been unwatered and cross-cutting has been started in two directions at the 200-ft. level.—The Mohawk Ledge Co., which is operating a lease on the Hedge claim of the Consolidated, formerly the Jumbo Extension, has let a contract to sink the shaft 200 ft. deeper. The lease has 221 days to run. At present the shaft is 175 ft. deep. Considerable work will be done on the 300-ft. level while the shaft is being deepened. At a depth of 200 ft. the shaft of the Consolidated Jumbo cut the vein. Favorable assays have been obtained. The vein is 10 ft. thick. A station is being cut and drifts will be driven in both directions.—On August 22 the third dividend of $90,000 was declared by the Engineers' lease on the Goldfield Florence, making a total of $270,000 to date.—The old Del Monte, two miles from Aurora, is now the property of the Cua Consolidated Mining Co. It consists of 20 stamps and pan amalgamation mill. The mine of the Company, 4800 ft. from the camp, has 20 stamps with an improved cyaniding plant. The Company contemplates changing the process and enlarging the mill to 50 stamps, using electric power.—The mines of Goldfield produced during the week ending August 22 a total of 2441 tons of ore, an estimated value of $23,350, of which production the production of the Tonopah mines amounted to 6300 tons of an estimated value of $165,550.

LINCOLN COUNTY.

W. H. Hunt is authority for the statement that the New York Searchlight Mines Co. will resume work some time early in September.—The installation of the gasoline engine has been completed on the Pioche-Pacific property, and two shifts have been started to work. The plant is modern in every particular and is gradually being sunk to a depth of several hundred feet.—A hoist is to be installed at the Georgia group, Eldorado Canyon, and as soon as it is running, the working force will be increased. The adit on the Dixey Girl claim has been extended 60 ft., making the total length 175 ft.—There is report, as yet unconfirmed, that the Black Hawk, in charge of E. F. Wilson, is to start work this month. It was on this property that a 10-stamp mill was erected about a year ago and immediately following the completion, for reasons never made public, the property was closed down and the mill never operated.

NYE COUNTY.

After a short interval the Jim Butler Mining Co. has again entered the shipping list, the shipments last week consisting of 200 tons to the Belmont mill. Regular consignments will be made in the future. The water pipe
for Round Mountains' new system has arrived and will be laid as soon as the trenches can be completed. The water will come from Shoshone.—It is believed that the capacity of the Spiral well at Round Mountain will be increased.—The Manhattan Mining Co. resumed operations at the Lemon mill, at Manhattan, last week. The plant has been completely overhauled, and, after the new tanks have been added, the initial run under the new management is being made on ore from the Shea lease on the Union No. 9. One hundred and fifty tons are being treated and it is expected that this ore will net an average of $150 per ton.—Stargo, a new camp about 50 miles northeast of Manhattan in the Monitor range of mountains, is attracting considerable attention. A number of Denver companies are operating and have found ore which assays all the way from $3 to $250.

WHITE PINE COUNTY.

The Sapho Mining Co., of which John Weber is manager, last week commenced work on the group of claims owned by the Company near Lane City. The shaft which is now down 41 ft. is to be sunk to the 100-ft. point without delay, after which the Company will decide on further development. The property joins the Elp Northern group and has indications that it contains good deposits of ore. Contracts are to be let at once for the building of the fourth unit of the concentrator at Smelter. The second unit of the plant is practically completed and the third will be in operation within six weeks.—The Nevada Northern railroad is to put in a siding to accommodate the Bunker Hill-Sullivan Mining Co. In particular, and the Granite mining district in general. The distance from the new siding to the shaft of the Bunker Hill will be about four miles.

OKLAHOMA.

OTOWA COUNTY.

(Special Correspondence.)—Recent drilling in the new Miami camp has extended the limits of the mineralized field to Narcissa, across the river. Three drills have struck ore. This makes the camp almost continuous from Baxter Springs through Quapaw, Lincolnville, and Miami, and now to Narcissa, extending it for 25 to 30 miles. The whole region is only newly developed, but is richer than most new camps and has been producing ore at an extraordinary rate. Within two weeks the three new mills at the Miami camp will be producing and will add materially to the output from the Miami Royalty Co.'s land. The new mills are the Index, the King Jack, and the Buckeye. The ground at all three mines is well developed and the ore is ready to be cleaned.—A good strike in the Jennie Mine has been made a short distance below the last week, when the shaft went down to the ore at 90 ft. Further development will be done as soon as the orebody is penetrated.—The Miami Yankee has secured a reduction of 11% royalty on its lease, the royalty now being 19%. The ground is well opened with 265 ft. of driving from one shaft. The ore assays 22% zinc-blende and galena. A mill will be built in the near future.

The new 172-acre lease of H. P. Hall, of Carthage, in the Miami camp has been divided into ten-acre tracts and is being subleased. Already five Carthage companies have been organized and have taken leases. A large number of drills are at work prospecting the land west of Miami and in the vicinity of Fairland some excellent indications of zinc-blende, galena, and other ores have been found. Drilling on Timmer hill has resulted in the finding of unusual ore at 800 ft. This is the fourth time that a good find has been made in this vicinity, but none have developed into producers.

Miami, August 22.

WASHINGTON.

OKANAGAN COUNTY.

(Special Correspondence.)—The tower adit on the Night Hawk mine is now in over 1200 ft. At the face an orebody, which has been followed nearly 500 ft., is 10 ft. wide. This is reported to be a valuable pay shoot, assaying well in silver and lead, with traces of copper.—Monroe Har- mon, manager of the Ruby mine, at the base of Mt. Chopaka, has returned from Ohio, where he has been consulting with his company on the construction of a mill. The principal stockholders of the Prizne Mining & Milling Co. are expected from Seattle. It is probable that work will be resumed on the Prizne mine. The main line of the Vancouver, Victoria & Eastern railway passes within a short distance of this property.

Nighthawk, August 15.

STEVEN'S COUNTY.

Announcement is made that the Silver-Lead Mining Co., operating near Metaline, will erect an ore roaster and crusher of sufficient capacity to handle the product of its mines. Work will be started this week. The roaster will be set up from the north fork of Sullivan creek and flumed to the claims. Ore cars and other equipment are on the ground. The Company is developing a group of four claims on the Pend d'Oreille river, a mile and a half below Metaline. An adit already started has exposed a body of extremely rich lead sulphides which assay as high as 35% lead and carry some silver.—Spokane mining men have organized the Blue Jim Mining & Milling Co., to take over a property of that name about one and a half miles from the Pend d'Oreille river, below Box canyon. The property was located 22 years ago, and it is said some of the handsomest specimens of gray copper ever shown were taken from the mine, but its owners were not progressive and never developed the property. Among those interested are C. S. Clute, of Spokane, and Charles E. Berry, of Belferka. The Company will develop the property.

GANADA.

BRITISH COLUMBIA.

Backed by a good supply of coke the B. C. Copper Co.'s smelter has been running smoothly without interruption by the Fernie fire. The smelter treated 13,615 tons of ore during the week ending August 15, as follows: Mother Lode, 9400 tons; Oro Denaro, 3622; other properties, 587 tons.—A. T. Carland and co-owners have given a lease and option on the Mountain Goint No. 2 and Lucky Boy mineral claims in the Jackson basin to L. R. McNiven, Henry Tyo, and Stanley Langille.—The Kootenay Development Co. has taken a lease on the Silver King mine and the Hall Mines smelter, at Nelson. The Company will change the motive power of all machinery to electricity.—For-rowing is the tonnage of ore shipped and crushed at the mines of Rossland for the week ending August 15: Centre Star, 3906; Le Roi, 1050; Le Roi No. 2, 490; total, 5440.

The machinery in the concentrator built at Trail has all been taken apart and some of it has already been sent to the St. Eugene mine. Some portions will be used in the several plants owned by the Consolidated Co. whenever it can be. This plant came into the hands of the Consolidated Co. when the Centre Star, War Eagle, St. Eugene, and the Trail smelter were amalgamated.

ONTARIO.

The Cobalt Central Mines Co. has begun diamond drill- ing in the Big Pete mine, to prove up the many veins which have been discovered on Diabase Mt., and ascertain the most direct and economical method of opening them up for production. The new vein recently found on the third level is about four feet wide and give assays running from 80 to 1000 oz. per ton. Cross-cutting has also begun from the bottom of the shaft on Lot 23, which is now down 117 ft. It is expected that an extension of the Crown Reserve vein will be cut at this level. These crosscuts will also open up other good veins that have been exposed on the surface, one of which shows surface mineral- ization for a width of 20 ft. that would run $20 per ton. Experience in the Kerr Lake district has proven that the richest ore in true diabase formation is found at a depth of over 100 ft. and it is expected that the work now in progress on Lot 23 will practically double the tonnage of ore available for treatment in the concentrator, the capacity of which has recently been raised to 100 tons per day.
Special Correspondence.

LONDON.

Weardale Lead Co. — Report of Mont Morgan Mining Co. — Output of Selukwe Mine, Rhodesia.

The Weardale Lead Co. is one of the most prosperous and promising lead propositions in Great Britain at the present time. It is situated in a district which has been well known as a lead producer for a great length of time, namely the tract of Carboniferous limestone country forming part of the Pennine chain of mountains between Cumberland, Northumberland, and Durham, situated about midway between Newcastle and Carlisle. The Company's mines are at the head of Weardale in the county of Durham. Operations were commenced in 1883 by the present company. For a good many years the results were not exactly profitable, but since 1905 the output and income have considerably advanced and the Company is now prosperous. This favorable state of affairs is due to the ability of the present manager, Mr. Errington Thompson. During the year ended June 30th, the produce of the smelter was 2370 tons of pig lead, and the profit £15,641; the next year showed an increase to 3230 tons output, and £39,194 profit. The result of the year's working for the year 1907-8 shows an advance in the output to 3519 tons of pig lead, but owing to the slump in metals the profit is only £19,220. Out of this profit £1000 is being placed to dividend-equalization fund to enable the dividend to be increased, bearing in mind that the company's dividends average 12% on the capital paid up, and a similar amount is being placed to capital account. The Company in 1900 had a capital of 97,919 shares of £1 each, of which only 15s. had been paid up, thus leaving a liability of 8s. per share. During the year 1906-7, 59791 was placed to capital-account, and the liability on the shares was cancelled. By a similar proceeding during the past year, the liability had been reduced between two and one half shilling, leaving a liability of only one shilling. In 1900 it was expected that the shareholders might have been called on to provide further working-capital, but the subsequent able development of the mine has relieved shareholders of this prospect, and has in addition provided out of profits an additional working-capital of nearly £20,000. Nor is this the only financial improvement which has been secured by the shareholders, the shares having been properly managed, for £100,000 of debentures have also been wiped out of profits. The mines are opening up well and the prospects are bright.

The report of the Mount Morgan Gold Mining Co. of Queensland for the year ended May 31st, shows a profit of £263,363 out of which £255,000 has been distributed as dividend. The ore mined during the year was valued at £321,000, 155,214 tons of ore were smelted, yielding 5219 tons of copper and 153,922 oz. gold, and the receipts were £351,723. The fall in the price of copper affected the profits, for during the first half of the financial year the average price obtained was £15, and during the second half 65. The result of the year's operations may be called an average one, for the variation in price prevented the profits from being either too inflated or depressed. The gold is obtained from three sources, namely, from the oxidized ores, from the sulphide ores by chlorination, and from the copper-smelting furnaces. From the first source the production was only 21,910 fine ounces from 123,469 tons, which is 3.4 dwt. per ton. This ore is rapidly being exhausted, and what remains is very low grade. Five years ago the yield was 79,456 oz. from 112,487 tons, and the average value has dropped in successive years to 10, 8, 7, and 5 oz. until it is now 3.4. Of sulphide gold ore 117,770 tons yielded 64,150 oz. gold, and 441 tons of copper. This yield of gold is nearly 11 dwt. per ton, and is practically at the same figure at which it has stood for five years. On the other hand, the improvements in treatment have yielded a considerable increasing output of copper. In the smelting department, where the average was 17 tons of copper, and 67,931 oz. gold. This is a considerable increase over the previous year, and it is due to the fact that a third furnace was started at the beginning of February. It is interesting to note that the output of silver ore made in 1905, when smelting was commenced, have proved remarkably exact. No further prospecting work has been conducted, but the ordinary mine development has opened up large bodies of ore which amount approximately to three million tons. In addition there are very large reserves of low-grade ore running 2½% copper and 1½ dwt. gold. At the present time it is not being worked. The Mount Morgan Mine requires large addition of fluxes, and owing to the exhaustion of fluxing ore in the mine, a great deal of barren flux has to be brought up. At the present time, with three furnaces in operation, the rates of consumption of ironstone and limestone per annum are 52,000 and 130,000 tons respectively. As I have before mentioned in this column the company has invested a large sum in the present improvements.

The Selukwe Mine, situated in the area of the Rhodesian gold mines. It commenced operations in 1898, and for a few years did pretty well on 14 to 15 dwt. ore. When the number of stamps was increased from 20 to 40 head, and a cyanide plant was added, the Company made profits sufficient to pay dividends. On the capital of £321,000 dividends of 10% were paid in August 1902, February 1903, and August 1903. This capital, is, of course, too much, but it is what we have been accustomed to the mining of the British South Africa Co. Some of the shares were issued at 100% premium, and the market quotation at one time stood very high. Unfortunately the grade of the ore has fallen off, and the output dropped from 50,000 bullion ounces in 1902 and 1903 to 26,288 oz. in 1904. During the year ended March 15, 1907, the output was 25,446 bullion ounces, which realised £87,906. Of this £15,517 oz. came from the batteries, and 5592 oz. from the cyanide plant. The average yield over the plates was 5.27 dwt. per ton, and from the cyanide plant 2.39 dwt. The working costs of mining and milling were £56,117, and of cyaniding £7291, leaving a mine profit of £23,588. In addition £18,764 has been spent in development, and £16,789 has been written off for depreciation, so that there is an adverse balance of over £2000. The development work has opened up increased bodies of ore, but the grade does not improve. The ore reserves at present amount to about 150,000 tons, which is equal to a two years' supply.

KALGOORLIE, WESTERN AUSTRALIA.

Developments in Great Boulder and Main Reef.—Wood-Cutters' Strike. —Local and Imported Coal.—Kalgoorlie Power Co. —Results of Electric tramway Operation.

The State's gold production for June totalled 2,900,000, to which Kalgoorlie contributed 1,700,000. So far this year, production is holding its own with last year, but a worse time for the gold industry is certain as the larger mines are reducing yields. Nothing out of the ordinary is reported in general development work, excepting that much interest is taken in the opening out at the 1500 ft. in the Kalgoorli, 1890 ft. in the Ivanhoe, and sinking the main shaft at the Great Boulder to 2400 ft. A great deal of speculation is rife as to the probability of the Great Boulder shoot dipping into the Main Reef property on the south end of the former. What appears to be the end of the shoot at 2150 ft. in Edwards' shaft is some 600 ft. north of the Main Reef boundary. Some people calculate that the latter lease will get ore at 3000 ft., others below 4000 ft.; anyhow such talk only tends to weaken the shares of the Boulder Co., while people are comparing it with Main Reef. A strike, not quite general so far, has occurred among the cutters and carters out in the bush, and if it con-
quires much longer the position of the mines will be serious. For the fuel supply of the mines here, several firewood companies have been formed, and they have laid down light railroad lines, from the main Government railroad, far into the scanty bush. About 1500 tons is the daily requirement of the mines, and few have enough room to carry over reserve of fuel, so if regular supplies cease, there is no alternative left other than媒, and the work is at work for the several firewood companies, and the trouble is that they want more wages for cutting, carting, and truck-loading, as well as some different arrangement about stores, board, and lodging. So far, the firewood people will not concede any of the demands of their employees. We have no coal in this State suitable for general use, but that the Collie field in the Southwest district is of very poor quality, and will not stand much handling. Even on the Government railways a mixture of Newcastle (N. S. W.) and Collie is used, although the drivers would prefer only the former; in fact, it is practically only the Government consumption that keeps the Collie mines going. During the last year or two experiments have been made with briquetting the local coal, and having trials made on coastal steamers. The former was hardly a success. Although there is a good deal of timber still standing that can be cut for fuel, the time will come when we must experiment with the local coal, or use that from New South Wales, or fuel oil from America and the East.

Early in June the rains filled the Mundaring reservoir, and on water is now running over the weir, so we have again 46,500,000,000 gal. of water on hand. This fills the dam regularly every year at about this time. During 1907 the Kalgoorlie Power Co. made a profit of $130,000. This company has a large plant of three vertical engines made by Stewart & Co., of Glasgow, with General Electric generators, one horizontal cross-compound engine by Toosi of Italy, with generator, and it is now putting in a fifth engine of about 1000 hp. The Company supplied power to the electric tramsways to the mines, and for private lighting in what is known as the Roads Board district, the municipalities of Kalgoorlie and Boulder City having their own large lighting stations. The 1907 report of the Kalgoorlie electric tramsways shows the following figures, in each case there is a fair decrease in the returns for 1906, due to local depression and keen competition with the Government suburban rail service:

| Car miles | 650,530 |
| Passengers | 2,052,241 |
| Power consumed, units | 930,231 |
| Cost of power consumed | $52,000 |
| Gross receipts | $240,000 |
| Net profit | $90,000 |
| Miles in operation | 2915 |

The output from the various mines for June was as shown below:

The milling grade of the ore at the Associated Northern is to be brought down to 8 dwt. per ton, in order to utilize the large amount of low-grade reserves.

MEXICO.

From almost every State of the Mexican Union come protests because of the proposed new mining law. Not only are these complaints made in connection with mining matters, but other industries are laying their troubles upon this measure for disturbing the serenity of foreign capitalists. Though the deplorable conditions began to manifest themselves as a result of the financial troubles of last fall, this is the proposed revision of the mining law that made public, nevertheless that must now be made an object lesson and bear the blame. Undoubtedly some important enterprises have been held up, and without doubt the present was an inopportune time to present the changes contemplated in the prohibitory articles in the new measure. All possible advantage is now unquestionably being taken of these articles to make them the scapegoat for the prevailing business difficulties. But as our troubles never come in single file, the miner may soon forget the proposed mining law in the consideration of others that are upon us, one of which is the new tariff on iron and steel which went into effect on August 15. It is in part as follows: plain steel bars 6c per kilogram (2.2 lb.) gross weight; worked and adorned steel bars and iron bars, 7c per kilogram gross weight; iron and steel rails, 21c; screws, clamps, joints, and nails for rails, 5c; steel beams and joists, 5c; joints, headers, and columns of iron, when therefore rated, 5c. This tariff is for the purpose of stimulating manufactures in the country and for the protection of the Mexican plants already in operation. Added to this is the effort, either on the part of home producers or of the railroads, to have freight rates on imported coal and coke raised by about $1 per ton, depending on the haul, as for example, from Vera Cruz to Mexico City, from $7.50 on coal to $8.50, and from $8.50 to $9.50 on coke; and from Tampico to Monterrey (which is nearer the great Mexican coalfields of the State of Coahuila) an increase on coal from $5.06 to $6.21 and on coke from $6.06 to $7.21. The rates quoted are now before the Government railway commission, but it is not believed such discrimination in rates will be allowed. It is stated that an effort to have an import duty placed on coal or coke would be quite futile, so the mines and smelters, which are the largest consumers of fuel, probably have nothing to fear on this score. The miner still has hanging over him the proposed increase in the freight rates of 10, 15, and 20%, respectively, in ores under $5 valuation, between $5 and $50, and over $50 valuation per ton, and which though held off now for many months will undoubtedly be fastened upon the shipper as soon as the general financial conditions and the metal markets will permit.

All of this, however, cannot seem to direct the attention from worthy enterprises and considerable new work is being carried out on all sides. Most noticeable during the month of August has been the number of concessions sought from the Federal Government for water-power on the various rivers throughout the Republic. Scarcely a day has passed that a request has not been made for water rights for power purposes in some one of the States of Chihuahua, Sonora, Sinaloa, Tepic, Hidalgo, Jalisco, Guerrero, or Puebla. In most instances they have been for mining enterprises. The great saving which has been effected in the camps, such as Guanajuato and El Oro, where the electric power from hydroelectric plants has been introduced, has brought the matter vividly before the public. In the camp of El Oro, State of Mexico, the replacement of steam by electricity has been the pioneer move, for Mexico, of the Dos Estrellas Co., which has decided upon electric locomotives for its railroad between the mine and the mill. It has ordered three for this purpose, which number will be increased later on. Another important improvement in the camp of El Oro is that of the Esperanzas Co.,
which is installing a plant of ten tube-mills, to which will be added twelve 'Puebcoa' agitation tanks for cyanide work. Improvements and additions have been completed the old tailing dumps of the Esperanzas company will be re-treated. The Deschindora is still working with promising prospects. The Chihuahua, as mentioned in a previous letter, hopes to resume at the same time as the Reina y Anexas Mg. Co. The English company, which had an option on the Victoria at $250 per share, has put off execution of the financial troubles, allowed its time to lapse, and the Victoria company has determined to continue searching for the Verde vein of the Dos Estrellas, which was lost by a fault. It will drive cross-cuts from both the Victoria and the Union shafts, which is estimated should not exceed 40 and 60 metres respectively, and should be completed in less than four months at a cost of $14 per yard. The money for this purpose was raised by selling the 165 forfeited shares to H. H. Simpson at $100 per share. The Victoria lies between El Oro and Dos Estrellas, and the great San Rafael vein of the camp is known to dip into the Victoria, at a depth of 2100 feet.

**CANANEA, MEXICO.**

With all the mines being operated, three of the four units of the concentrator run plant running, and four of the eight new blast-furnaces with two converters and the reveratory furnace in operation, the resumption of work at Cananea is well under way. At present the total number of men employed is about 2700, of whom 2970 are Mexicans, and 630 belong to other nationalities, mostly Americans. These men are distributed among the different departments as follows: mining, 1500; narrow-gauge railway, 400; concentrator, 240; metal-car, 150; construction, 200; with the remainder in the mercantile, accounting, and bank departments, and under the head of miscellaneous. Wages for all classes of labor are considerably lower than before the shut-down in November, in general white men have been cut 50c. per day. As an illustration, mechanics formerly received $4.75 for 10 hr., while now they get $3.50, while helpers have been reduced from $3.50 to $3 per day. Mexican labor runs from $1 to $2.50 gold, governed by the class of work. On all outside common labor, where very little skill is required, such as shoveling, running cars, and roadbuildwork, they receive $1 for 10 hr., and the scale varies from that up to $2.25 for the highest-paid men in the mines, with a bonus of $50 if they work 26 days per month. Aside from this general reduction in wages the efficiency of each man is greatly increased; this is due partly to the more active and progressive tone in the camp, and partly to the fact that there is an abundance of labor of all classes, so that more can be demanded of the men.

The mines are at present shipping about 2200 tons of ore, iron, and silica to the concentrator and smelter per day. Of the 2200 tons, 1650 tons are sent to the concentrator. Of first-class ore 455 tons are sent directly to the spreading-beds and 200 tons of iron and 65 of silica for flux and converter-lining respectively. In addition to this there is some lime-rock put onto the spreading-beds, the amount depending on the per cent of lime already in the mixture, mainly in the Elisa and Puertocitos ores. The Cananea-Duluth mine is probably receiving the greatest amount of attention just now, about 350 tons of ore being shipped daily, of which 260 tons are being mined and the remainder taken from the dump. Until recently the entire output has been going to the concentrator, but now shipments of first-class ore directly to the spreading-beds have been started. The mine is being worked with two narrow-gauge railways, and about 100 men on the mining used almost exclusively is back-stopping, taking out 100-ft. sections. The ground holds well, round stulls, supporting the back as the stope is carried up, being the only timbers required except the regular chute and raise-timbers. The ore as shipped carries from 2 to 4% copper, 5 to 6 oz. silver, and 60 to 80c. gold. The Overnight mine is producing about 500 tons per day, both first and second-class ore. Here the top-slicing system of mining is in use, caving the ground as the slices are carried down. The ore is worked in 65-ft. blocks. The ground is soft and caved readily. The Victoria mine is producing about 125 tons per day, where the ground is harder, and is worked in blocks of 45 by 55 ft. by the caving system. There are at present 13 of these blocks of ore, broken down ready to be drawn out, the thickest of which, from top to bottom, is 165 ft. The other two producing mines are the Elisa and the Puertocitos, the Elisa with underground workings, while the Puertocitos is an extensive surface creboby, the former an 80% copper, the latter 37%. The concentrator, which consists of two mills of two units each, is handling a good tonnage, but is not being pushed. All of the new mill is running. It has a daily capacity of 750 tons per unit. One unit of the old mill, which has a daily capacity of 500 tons per unit, is also running. The ore handled carries from 2 to 5% copper, and averages about 60% in copper. The ore is immediately conveyed to the ore-dump and dumped by means of a tripper moving rapidly from one end of the bed to the other. The tonnage and a complete analysis of all material as it is laid down on the beds is known, so that any smelting mixture that is desired can be had. There are three of these spreading-beds, each with 10,000 tons capacity. From the beds the ore is handled by a new type of reclaiming machine, the concentrator, and by the sorting and preparing of the ore, putting a mixture of 65 to 80% copper, iron, and lime are delivered by means of narrow-gauge cars into bins at the sampling mill. From these bins they are carried by means of conveyor-belts into the mill, where, with the exception of the concentrator which is sampled at the concentrator, they are carefully sampled. Passing through the mill by a system of conveyors and chutes onto another conveyor, the ore is first sorted and then送到 spreading-beds and dumped by means of a tripper moving the ore to the opposite end of the bed. The ore, in turn, is delivered to the concentrator, which is the ore on one side of the machine onto a conveyor belt; the other machine advancing the machine into the ore-pile. The capacity of this reclamer is large, as the four furnaces are supplied with one machine more than is needed, the other working at 80% capacity. So far these reclaimers have given considerable trouble on account of break-downs owing to small faults which are rapidly being overcome as the machines are becoming more perfected. The inventor, who is also the engineer for the manufacturers, the Robins Belt Conveyor Co., is on the ground, and there is little doubt that the reclaimers will within a short time be operating so that there will be no further trouble. The ore is conveyed to the anode-cathode reclaimers, and discharged by means of another tripper into the steel bins over the furnaces from which it is fed directly into the furnaces.

The four blast-furnaces, which are in operation, are handling between 1500 and 1600 tons of charge daily. The date for blowing-in additional furnaces is not yet decided. When the new system of feeding the furnaces is operating the furnace expenses are greatly reduced, ten men per furnace having been cut off.

The flue-dust from the furnaces is run in cars to the reverberatory, which is handling about 150 tons daily. Oil from the Texas oilfields is being used for fuel in place of the finely-ground coal in use before the shut-down, and is giving good results. The copper-contents is about 190 barrels per day. Two converters are being blown continuously. The copper-production at present averages about 57 tons daily.

Within the last few days the boilers at the main power- house have been using oil, and within a reasonably short time oil will be in use throughout the entire plant. The oil will be supplied at half the current price, and the same increase in output will result. The current is fed by gravity to the power-house, and the current will be supplied by the concentrator, and will be pumped up to the old mines. A third, rail, making it a standard-gauge track, is now being laid.
to the Cananea Central mines so that oil can be delivered there directly. As far as can be learned the management of the company is well pleased with the showing made so far in all departments.

**BUTTE, MONTANA.**

North Butte Mining Co.'s Developments.—Great Falls Smelter to Re-open September 1.—Pittsburg & Montana New Concentrator.—Montana Mine Owners' Association.—Panhandle Smelter to Blow-In.—Reins Co.'s Bond Issue.—Raven Mining Co.—A Schoolmistress in Rawhide.—North Butte Extension Issues Bonds.

The North Butte Mining Co. has started cross-cutting for the Edith May and Jessie veins from the 2000 and 2200-ft. levels of the Speculator. The stations and skip-pockets were completed during the past week, and the Edith May vein, because of its dip to the south, was cut in one corner of the station at the 2200-ft. level. The vein has not yet been fully cut through at that point, but the portion opened shows that vein to be of the same character as it is at 1800 ft., where the Company has been mining chiefly during the past two years. At 2000 ft. the vein is less than 100 ft. from the shaft. In a short time the Edith May will be opened on both the new levels, and 400 ft. of additional stopping-ground added to the company's ore-supply. A long cross-cut will be necessary to reach the Jessie vein, which lies north of the Edith May, with the Granite Mountain, owned by the Lewishons, between. Two veins at the two levels are driven through the Edith May and Granite Mountain into the Jessie.

By the first of the month the repairs on the damaged smelter of the Boston & Montana Co. at Great Falls will be finished, and ore shipments to Black Eagle Falls will be resumed, but not more than 1000 tons per day will be added to the present output. During the shut-down of the Great Falls plant the Washoe smelter at Anaconda has been overcrowded to the extent of nearly 2000 tons per day, and that plant will be greatly relieved. With a resumption of operations at Great Falls and all the mines of the Boston & Montana Co., the Butte district ought to make another record for copper production, as everything will be running at full blast, with the exception of the St. Lawrence mine of the Anaconda Co., which is still unable to attract noticing. The prevalence of gas in the upper levels, coming from the fire which has been burning in that property since 1889.

The Pittsburg & Montana Co. has completed its new 390-ton concentrator-building and is installing the machinery. The Company will soon increase its output, and with the concentrator will be able to work a lower grade of ore. The Davis-Daly Estates Copper Co. is confining its work to the Colorado shaft, which is being sunk deeper. It is now about 1200 ft. deep. Ninety feet was sunk in July. No mining is being done, and only a few lessees are engaged in the Plymouth and Silver King mines.

Something seems to have gone wrong with the Montana Mine Owners' Association, which was organized to fight the smelter trust. A working committee was appointed and instructed to secure the Panhandle smelting plant at Fonderay, Idaho. Progress was reported, and the independent mine operators in Montana were notified to get ready for ore-shipping. Various dates were set for blowing-in the smelter, and then all talk ceased and the committee and the officers of the new association became so silent as to attract notice. Evidently the men in control of the new association have gone out of the business of trust-fighting. The latest information is that the Greenoughs, owners of the Snowstorm mine at Nullan, Idaho, have secured control of the Panhandle smelter and will start it up soon. It is stated that a large deposit of iron ore on Lake Pend d'Oreille goes with the smelter, which will provide flux for the Snowstorm copper ore. The Greenoughs have no smelting facilities, and have been able to sell the Snowstorm ore only as it was wanted by the Washoe and other smelters for converter-lining. Now the Greenoughs appear to have solved their smelting difficulties, if the story of the big iron-ore deposits is true. The Panhandle smelter will be able to handle 250 tons of ore per day, and the Snowstorm can more than supply that amount, so that the Montana Mine Owners' Association will have to do some more financing.

The Copper Eagle Mining & Smelting Co., which owns a sliver property north of Butte, has resumed operations after a long shut-down, having raised funds needed to carry on development work. The shaft will be sunk 100 ft. additional. A good body of ore has been found on the 250-ft. level.

The stockholders of the Reins Copper Co. have voted to issue $500,000 in 5%, five-year, first-mortgage bonds. The mortgage will cover all of the Company's property in Butte, including the Combination, Ellis, and Louise quartz lode claims, and all the equipment. The special meeting was largely attended by local stockholders, and some opposition to the bond issue was manifested, but it was represented that it was a bond issue or a re-organization of the Company. Nearly all of the Company's stock was represented, a large majority being voted by proxy by Secretary W. F. Johnson, who came from Pittsburg to attend the meeting as the representative of Colonel J. H. Guffey and his associates. About a year ago the capital stock of the Company was increased from 1,050,000 to 1,500,000 shares of the par value of $1.50 per share, but that did not meet the necessities of the Company. Colonel Guffey and his associates have a great deal of money in trying to develop his copper-producing mine, but the big and rich Colusa-Leonard vein, for which they were searching, proved elusive, and while some good ore has been found on the 1200-ft. level it is not extensive. About two years ago the stock of this Company sold at about $3 per share, and last February it sold as low as 8c. per share.

It is now quoted at 40c. again.

The Raven Mining Co. is not sinking the shaft deeper on the Raven claim, but is engaged in sinking a winze on the shaft at the 1100-ft. level. Two veins were cross-cut and considerable driving done on the best of the two. Some encouraging assays were obtained, but the copper was not present in paying quantity. The vein will be explored at greater depth through the winze. The shaft is an incline, and the 1100-ft. station has a vertical rise of only about 750 ft. and the vein is in the middle plain near the machine-drill workings of the Anaconda Co., presumably from the Buffalo mine.

Miss Margaret Laughlin, formerly a school teacher in Butte and county superintendent of schools for four years, has become a mine operator and newspaper owner in Rawhide. She was reared about the mines of Butte and acquired a broad and technical knowledge of mining, which she has put to good use in Nevada. She has been back in Butte for several weeks, and there is no one from Nevada that is a greater booster for that State than is Miss Laughlin. She says Rawhide has been "knocked" by the envious and malicious, but in her opinion it is the greatest gold district in Nevada. "The trouble with Rawhide," she says, "is that the town outwore the mines, and as the number of miners has been cut down the financial panic came and it hit Rawhide as badly as any place, but the mines are getting better every hour. Development work has been started and in a short time the winzes go down. Rich ore is being taken from the Kearns No. 2 lease at a depth of 300 ft., and the shaft is in the same character of ore 25 ft. deeper. New strikes are made almost daily, and we now have 20 winzes. The number is constantly growing. The Kearns lease was purchased for $35,000, and the profits paid for it in less than a week. Some of the richest ore in the camp was found at a depth of three feet in the Grutt Hill Mill." Miss Laughlin is also interested in Goldfield. She owns a tenth interest in one of the best mines in Rawhide, and has interests in others. She is also half owner of the Press-Times Publishing Co. E. W. King, once owner of the somewhat noted Barnes-King
mine of Montana, is also largely interested in Rawhide and has been in Butte for several days. He is said to have purchased the Balcon property in Rawhide for $125,000. Mr. King disclaims any connection with the notorious Barnes-King deal.

It is announced that the financial difficulties of the North Butte Extension Co. will be met by the issuance of $400,000 in bonds, bearing 6% interest, maturing in five years. Some of the large stockholders are ready to take $200,000 worth of the bonds at once. The remaining $200,000 will be retained in the treasury. The Extension Co. owes a considerable sum of money on unpaid operating expenses and options, but it is said these will soon be paid, and operations on the property will be resumed.

Butte men are engaged in exploration in a new copper district, in Jefferson county, 16 miles from Butte, and 11 miles southwest of Boulder. The first company organized to work there is the President Copper & Gold Mining Co., incorporated under the laws of Montana and capitalized for 1,200,000 shares of the par value of $1 per share. The Company takes over 11 claims on which Dr. Ferdinand Grattan, of Butte, has been doing development work for a year or more. The claims are located along a vein for a distance of a mile and a half. The vein on the surface is from 30 to 60 ft. wide, and has been explored by two shafts sunk 3000 ft. deep. One is 210 ft. deep, and the other 50 ft. The officers of the Company are: President, Ferdinand Grattan; vice president, C. S. Shoemaker; treasurer, Walter Tallant; secretary, Joseph Chauvin. These, with William Creden and H. P. Bennet, constitute the board of directors.

SALT LAKE, UTAH.

The United States Smelting, Refining & Mining Co. is seeking to draw ores from the channels which have heretofore supplied the Selby plant near San Francisco. No sooner had word gone out that the latter would be closed because of trouble with smelter furnaces, a condition which forced no less than three copper smelters in the Salt Lake valley to the scrap pile, than emissaries of the United States S., R. & M. Co. were dispatched to the field seemingly left temporarily without a market. While some ores have been obtained, it is said, their efforts have not been entirely fruitful of results. The fact is, and this probably accounts for the unsuccessful mission of these agents, the Murray smelter of the American Smelting & Refining Co. could handle a very much larger tonnage than it has been doing for some months past; hence it is reasonable to presume that patrons of the Selby smelter will be taken care of elsewhere in one of the so-called "quagmires," if not A. S. R. plants—preferably at Murray. This smelter has scarcely been operated at more than half its capacity since the beginning of the present year. The building of the smelter in Tintic by the Tintic Smelting Co., which is just being placed in commission, has cut off a large tonnage from the Tintic district, which in the past has been the chief source of supply for the Murray plant. A. S. R. are not expected, however, that the question of a new contract with the Utah Consolidated will be definitely determined before the end of September, when it will be decided whether the Utah Consolidated shall go to the expense of building a smelter to take the place of the one made idle through the operation of an injunction of court. The lead department of the United States smelter is operating four furnaces under an oxidized charge, and has also several roasters in the battery of converter roasters working on sulphide ores.

It has been ascertained at the offices of Samuel Newhouse that the Boston Consolidated mine will be prepared to contribute 1600 tons of porphyry-ore to its Garfield mill by September 15, and accordingly, the mill management is making four additional sections in readiness to receive it. This is taken as an indication that the management of the Garfield smelter will have overcome by that time some of the difficulties noted hitherto. With these other units in service the Boston Consolidated should produce from 1,000,000 to 1,200,000 lb. of copper in October. The August production will aggregate a little over 700,000 lb., and 491,469 lb. in July. The entire tonnage of 21,500 dry tons of porphyry-ore sent to the concentrator, and 603 tons shipped direct to the smelter. The July mill extraction was 65.5%, 16.5 tons being concentrated into one.

Mining conditions in Beaver county show material improvement. An evidence is seen in the acquisition by a syndicate of Utah mining men of the large interests to the Horn Silver mine at Frisco, in the organization of the King David Mining Co., with the commencement of development upon a large scale, and in the consolidation of the Cedar and Tallman mines. In the Cactus mine of the Newhouse Mines & Smelters corporation, development carried to the 900-ft. level has revealed the orebodies which had been exploited on the upper levels. The company is milling from 15,000 to 20,000 tons of ore monthly, shipping some crude ore direct to the smelter, and producing about 500,000 lb. of copper per month. A consolidation of the Wasatch and Skyfark copper properties has also been effected, while numerous other mines in the county are active. Outside the Horn Silver and Cactus, the Moscow is a leading shipper, producing considerable ore. The Majestic Mines Co. is doing some effective work at the O. K. mine, which has produced considerable high-grade copper ore in the past.
Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Wages of watchmen have generally been adjudged as applying on annual assessment work when the mine is idle, or when there is portable property needing protection.

Solder for gold consists of 14 parts gold, 6 silver, and 4 copper. Silver-solder may be either 70 parts yellow brass, 7 zinc, and 11½ tin; or 145 parts silver, 73 brass (3 copper, 1 zinc), and 4 zinc.

The alternate-shovel method of sampling ore is cheaper and quicker than the coning and quartering method, and is apt to give a closer approximation to absolute accuracy, unless the evening is very carefully done.

Road work, if done for the actual benefit of a mining claim, may be counted as annual labor, but if only for the benefit of the district adjacent, even though it be on the claim, it has been held that it could not apply as annual labor.

The relative strength of beams is given by the ratio of the products of the breadth and the square of the depth. Thus, if it be desired to see whether a 4 by 6 in. timber will make as strong a joist as a 2 by 8 in., the method is as follows: \(4 \times 6 \times 6 = 144\), and \(2 \times 8 \times 8 = 128\); therefore the former is 1.12 times stronger than the latter.

Gold is reported by a correspondent as occurring upon mica in the form of a film. In answer to the question whether such an instance has a parallel, we must confess that the ease evidently stands alone. It may be true; there is no reason in the world why it might not be; but previous occurrences have no bearing upon the matter. 'Gold is where you find it'; it is either on that mica, or it isn't. An assay will give the answer, and no other answer is worth anything.

The velocity of flow from an orifice is theoretically the same as that acquired by a body falling from rest in a vacuum through a height equal to the head of water on the orifice. Practically this value is never reached, and for orifices with sharp edges in thin plates, the actual velocity of flow in feet per second is \(C\sqrt{2gh}\), in which \(C\) is a coefficient varying between 0.97 and 0.99, \(g\) is the acceleration of gravity in feet per second (32.16), and \(h\) is the head, in feet, on the centre of the orifice.

Candle-power is a definite unit, fixed by law in civilized countries. The British unit of light, or candle-power, is the amount of illumination given by a sperm candle ½ in. diam. burning at the rate of 120 gr. per hour. An international congress held in Paris in 1890 established a light-unit, known as the 'decimal candle,' which is the amount of illumination from the one-twentieth part of a square centimetre of molten platinum at the temperature of solidification. This unit is equal to 1.02 British candle-power.

The metre, the standard unit of length of the metric system, was intended to be one ten-millionth part of the earth's quadrant, that is, that portion of a meridian embraced between either pole and the equator. The original measurements and calculations, made by La Condamine in Ecuador, South America, in 1745, by means of which the standard metric-bar was prepared, have been found to be slightly in error, but the length of the standard remains the same. A re-measurement of a meridian at the equator was made a few years ago by another French commission of astronomers.

The 'Eads mud-pump' was designed by the builder of the St. Louis bridge for use in the caissons of that structure. The principle involved is the same as that employed in the atomizer and the injector, that is, the principle of the induced current. The mechanical arrangement is such that a stream of water with a high velocity is discharged on the outside of a small pipe, which produces a partial vacuum in the latter, when the pressure of the air on the outside forces the mud through the small pipe and into the current of water, by which the mud is carried away. The current of water is the motive power which carries away the material, the induced current being used only to deliver the mud to the discharge pipe. At the St. Louis bridge a pump of this design with a 3½ in. suction was capable of raising 20 cu. yd. of material 120 ft. per hour, the water-pressure being 150 lb. per square inch.

The Venturi meter is the only practical device for measuring the flow of water through a large pipe. It is available for mains up to 60 in. diam., and by means of an ingenious automatic recording-apparatus a continuous record may be had of the exact rate of flow at any moment. The Venturi meter causes less loss of head than any other style, and since it has no moving parts, is less liable to clog and inactivate the system. In its essential form the Venturi meter consists of a simple contraction of the area of the main to about one-ninth of its full area, and hence the velocity through the throat is nine times that in the full section. Piezometer tubes inserted at the throat and at the full section of the pipe just ahead of the throat, show the actual difference of head due to the difference of velocities, and if no loss of head between the two sections be considered, the quantity of water flowing is dependent only upon the difference of the heights in the two piezometer tubes. In practice there is a small loss between the two sections, and hence the actual discharge is slightly less than the theoretical. The Venturi meter, so-called in honor of the distinguished hydraulician who first developed the principle by which it operates, was invented by Clemens Herschel in 1887. The cost of these meters is about as follows: for the 6-in. size, $600; 12-in., $770; 24-in., $1130.

Discussion.

Readers of the Mining and Scientific Press are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

The Rights of the Miner.

The Editor:

Sir—In relation to that most readable, instructive, but somewhat fallacious article by Theo. F. Van Wagener, on 'The Rights of the Miner,' in your issue of May 16, I make the following brief comments. A 'tax for right to prospect' is, after all, a small matter, merely a nominal charge of 10s. or so, obtainable by all desirable persons, and bestowing on each recipient the right of prospecting or owning property. In the United States, on the other hand, where there is no such privilege, what do we find? No one, except with the rights of citizenship, full or partial, can hold against a claimant any unpatented mining claims. Surely the small charge for a 'miner's right' seems worth the money to an alien and is a light tax to a citizen. As for labor conditions. Take, for example, Western Australia, where the labor conditions are severe, necessitating one man, costing about £3 per week, to each 6 acres, and after approval, one to every 3 acres. The 'law of the apex' cuts little figure to the prospector in such a country compared to such onerous labor-conditions. Yet as far back as 1903 we find Western Australia overrun by as hardy a race of prospectors, or 'diggers' as they call them there, as any 'sour dough' that ever tossed a 'flapjack,' or 'humped his way' in the Western State. That prospecting in that part of Australia has not been more general in recent years is not because the digger does not enjoy the blessings of the 'apex law,' but because he is cursed with such labor-conditions. Compare the $100 per annum, and no necessary record of work performed in the United States. In the latter country the work may be omitted for years it may be, with next to nothing done, without forfeiture, whereas, in the other instance, one day's omission, without 'exemption' renders any claim forfeitable, and neither is there such fixity of tenure as patenting gives. Such countries, if they suffer today from a dearth of the true genus 'prospector,' do not suffer because of any lack of the 'apex law,' or because vertical side and end-lines are in force. It is a matter of onerous labor-conditions, excessive royalties, and the like. In South Africa the country is either held by large syndicates, or the laws are expressly favorable to capitalists, so that the prospector by restrictions of search and absurd royalties is not given a fair show. I am under the impression that Rhodesia has, or had, the 'extra-lateral' law. However that may be, the poor prospector finds little encouragement, and usually leaves in despair or disgust. Siberia is another instance of a vast country, with immense mineral resources, effectually locked up either by large grants or impossible conditions and restrictions upon the foreigner. I have no doubt, from long custom, the prospector has a decided preference for this law, fancying he will be defrauded from his rights by any change to vertical side-lines. This, in most instances, is purely imaginary. Let go of the absurd restriction of 'finding mineral in place' on Government mineral lands; let the claim be 'pegged' without reference to any supposed 'discovery,' so that the dip of the lode can be protected by the full width of the claim. Then if the prospector is still unsatisfied, let him take up as many 'deep' claims as he chooses. He will have all the more to sell, when he has proved the worth of his outcrop claim, or when some capitalist has proved it for him.

Why I have characterised the article as 'fallacious' is mainly because the deductions seem illogical. For instance, the author states in effect: The apex law is the only law favorable to the prospector, under which he can sell his claims. The prospector does not and cannot develop his property in depth; he is too poor; or he has not sufficient skill. The capitalist, or investor, favors the vertical quadrilateral claim, as he knows what he is buying, and what he is not buying. Why need the prospector worry about the vein in depth, seeing that he will never develop it? On the other hand, the capitalist favors the vertical claim. It would appear that the interest of both buyer and seller are identical, and that both are served by the vertical sideline.

SALT BUSH

Cyanidation in Mexico.

The Editor:

Sir—I have read with much interest the article by F. J. Hobson on 'Cyanidation in Mexico,' which appeared in your issues of August 1 and 8. The extraction of silver from sulphide ore is of special interest to me, as I believe I was the first cyanide chemist sent into Mexico. In 1891 the Mexican Syndicate sent W. H. Trewartha James and myself to Mexico to investigate the field for cyanide work. I had a portable assay-outfit and testing-plant, and did a good deal of work on ores from various parts of the Republic. At that time practically nothing was known as to the treatment of silver ores, and I had no data to guide me. I found that by using a sufficiently strong cyanide solution I got a good extraction on ores containing argentite, and that by using an oxidising agent with the cyanide, in many cases a very high extraction was obtained. On ores containing antimonious and arsenical sulphide minerals the extraction was never good. Owing to ill health I left Mexico in 1892, and did not subsequently have any opportunity of continuing the work on silver-ore treatment. The prospectus of The Mexican Gold & Silver Recovery Co., Ltd., contained my report on the treatment of Mexican ores, in which special stress was laid on the suitability of silver ores to cyanidation, while comparatively little reference was made to gold ores. The Company was floated late in 1892 or early in 1893, but it is only during the last few years that the cyanidation of silver ores has received attention.

The extraction of silver from its antimonious and arsenical sulphide minerals without previous roast-
ing was a difficult problem, and by solving it, Mr. Hobson may claim to have introduced what is practically a new process. In explaining the reactions that take place in the solution of these silver compounds in cyanide in the presence of compounds of mercury, the Mexican metallurgists do not agree with the standard chemical authorities." According to Roseee and Schorlemmer’s ‘Treatise on Chemistry,’ Vol. 2, page 321, “mercurous sulphide does not exist.” Then either Mr. Hobson’s equation showing the solution of silver sulphide in his hypothetical mercurous poison cyanide is incorrect, or the authorities are. Mercure cyanide is soluble in water, and in this respect differs from the cyanides of the other heavy metals. It is, therefore, not necessary to consider that when a mercuric salt reacts with potassic cyanide, a double cyanide is formed. It can, in fact, be demonstrated that, if potassic cyanide and calomel be made to react according to the equation quoted by Mr. Hobson,

\[ 4KC\text{y} + \text{Hg}_2\text{Cl}_2 = K_2\text{HgC\text{y}} + 2\text{KCl} + \text{Hg}, \]

in presence of oxygen, the reaction proceeds further until all the cyanogen is combined with mercury;

\[ 4KC\text{y} + \text{Hg}_2\text{Cl}_2 + \text{O} + \text{H}_2\text{O} = 2\text{HgC\text{y}} + 2\text{KCl} + 2\text{KOH}. \]

The authorities state also that mercurous cyanide does not exist. The decomposition of ferrocyanide by mercuric oxide, or a mercuric salt, is well known as yielding all the cyanogen as mercuric cyanide. Mr. Hobson’s discovery that the silver-bearing amonious and arsenical minerals, stephanite, pyrargyrite, and proustite, are soluble in cyanide solution containing a compound of mercury, and an excess of alkaline hydrate, is of great interest, and will prove of great value in the treatment of these important silver minerals. It is not possible, however, for calcie thio-antimonite, which consists simply of a solution of antimonious sulphide in calcie sulphide, to exist in solution with silver cyanide. The silver would be precipitated as sulphide. I would suggest that the reaction may go along the following lines: the first step in the reaction or series of reactions may be taken as represented by the equation given by Mr. Hobson as to the reaction with stephanite, but I would prefer to state it thus:

\[ 2(5\text{Ag}_2\text{S} + \text{Sb}_2\text{S}_3) + 10\text{HgC\text{y}} + 2\text{KCl} + 4\text{Ca(OH)}_2 \rightarrow 20\text{KAgC\text{y}} + 10\text{HgS} + \text{Ca}_4(\text{Sb}_2\text{S}_3)_3 + \text{Ca}(\text{SbO}_2)_2 + 4\text{H}_2\text{O}. \]

It is well known that antimonious sulphide is soluble in alkaline or alkaline-earth hydrate solution forming a soluble thio-antimonite and an antimonite, as given in the equation by Mr. Hobson. In the presence, however, of a compound of a metal, the sulphide of which is insoluble in cyanide solution, for example, lead or mercury, the thio-antimonite is decomposed. The reaction may be stated thus:

\[ \text{Ca}_4(\text{Sb}_2\text{S}_3)_3 + 3\text{HgC\text{y}} \rightarrow 3\text{HgS} + \text{Sb}_2\text{S}_3 + 3\text{CaC\text{y}}. \]

The antimonious sulphide then reacts with some more of the calcie hydrate, again forming thio-antimonite and antimonite, thus:

\[ 2\text{Sb}_2\text{S}_3 + 4\text{Ca(OH)}_2 \rightarrow \text{Ca}_4(\text{Sb}_2\text{S}_3)_3 + \text{Ca}(\text{SbO}_2)_2 + 4\text{H}_2\text{O}. \]

The thio-antimonite would then be decomposed as shown by equation 8, and the series of reactions would proceed until all the antimony existed as antimonite, and all the sulphur as sulphide of a metal insoluble in cyanide. Only after all the antimonious sulphide in solution has been decomposed will the silver go into solution as cyanide. As a highly alkaline solution of antimonite has strongly reducing properties, it is evident it would not be a good solvent of metallic gold, and this emphasizes the difference between the treatment suitable for the extraction of gold and that for silver. Referring to the action of a strongly alkaline solution of cyanide on gold ore, it is well known that the solution of the gold from a sulphide ore is incomplete, owing to the formation of alkaline sulphide in the solution. It is also a fact, though not so generally known, that in the case of a thoroughly oxidized ore, quite free from sulphide, the extraction of the gold is greatly retarded by the use of a strongly alkaline solution of cyanide, such a solution taking three times as long to dissolve the gold as a neutral one or one slightly acid from the presence of HC\text{y}. The results given by Mr. Hobson of tests on gold-silver ores containing argentite, proustite, and pyrargyrite can, I think, be accounted for from the reactions of compounds whose existence is well known, and without calling into being compounds such as mercurous sulphide and mercurous potassic cyanide, which are not found to exist under any other conditions.

Stronger proof than the ‘negative probability’ given by Mr. Hobson will be required before the existence of these compounds will be accepted. Little progress has been made in the development of the technical application of the chemistry of the cyanide process, compared to the mechanical improvement. Most cyanide chemists and managers have little leisure and few appliances for research work. Articles giving the results of original research work on the chemistry of cyanidation are rare, and one like that by Mr. Hobson should be greatly appreciated by the profession.

San Francisco, August 15.

BERTRAM HUNT.

Professional Ethics.

The Editor:

Sir—Of late there has been in the Mining and Scientific Press much discussion of professional ethics, and I would like to have opinions on the following points which are puzzling to the young men of the profession. Suppose a young engineer to have been connected with a mining company in a capacity such that he became well informed about the district, and much more so about the company’s property. After leaving the employment of this company he is consulted by other parties who are being solicited by his former employers to buy stock in their company. Knowing him to have been employed by the company in question, the prospective investors consult him. Is it proper for the engineer in that case to use the information he possesses in advising his clients? The situation is complicated by the fact that his clients do not intend to invest such a large sum as to make it worth while to have made a thorough new examination, and furthermore, the condi-
tions at the mine remain the same as when the engineer was employed by the company.

Suppose, again, that an engineer's clients have under option a property in a district which the engineer has previously examined, but, being only a prospect, he would have to use his knowledge of other properties, including especially that of his former employers, to render his opinion upon the district, and that this opinion would indirectly condemn the property at which he was formerly engaged!

This is one of the situations with which young engineers are apt to be confronted, and especially those working for small companies. Opinions on these points expressed through your columns would materially influence many.

Constant Reader.

San Francisco, August 5.

The Editor:

Sir—the discussion upon professional ethics in the Mining and Scientific Press is most interesting, and will surely lead to good results. It seems as if we might be a great deal more rigid in this matter without detriment to the profession. For instance: Is it right to discuss or criticize a brother engineer's report when it is palpably garbled? I speak feelingly, for I have just passed through such an experience. Garbled and incorrect extracts were taken from a report I had made, and these extracts were placed in juxtaposition, so as to be entirely misleading, and then sent, without my knowledge or consent, to a number of engineers, who were invited to privately criticize and discuss the subject. Some wrote me about it, others declined to answer directly, and others furnished their ideas.

A courteous public discussion is a good thing, but should we discuss excerpts unless they are made with the author's consent? Even then it may be unfair to the reporting engineer, unless the abstract is not at all modified by the balance of the report. It seems to me that good ethics should make us refrain from answering in such a case.

Wheeling, W. Va., August 14.

Ethics of Technical Writing.

The Editor:

Sir—Allow me to submit a few words on the subject of technical writing. It seems to me that if anyone has desirable information which he is willing to publish, such information should be as detailed and as truthful as possible. I have noticed, during the past few months, several articles published in various papers stating that certain mills had been started and had run for a period of, say, six months, during which time the average daily extraction, or the indicated extraction, or the actual extraction (as per bullion produced) amounted to some figure like 93 or 95%. I claim that an article which gives any one such figure, and one only, is misleading, for the reason that the average daily assays, on which is based the indicated extraction, may show 95%, while the actual percentage, as per bullion produced, may be only 70%. I believe that in every case of this kind the indicated extraction and the actual recovery should both be given, and if there be a great discrepancy between the two, some plausible reason should be given, or if an excuse can not be given, the article should be suppressed as being worthless. In cases where, for business reasons, dollars and cents, and questions of profit and loss, can not be entered into, at least all percentages and other data can be given accurately. As I understand it, such an article should be written to give others the benefit of experience gained, to bring out the actual truth instead of concealing it, to allow others to profit by avoiding mistakes that may have been made, as well as to call attention to special improvements and mechanical appliances which have been made use of.

In my experience I know of plants which have been able to show an actual recovery of only 65%, and of others, among them a plant treating 500 tons per day, where the actual extraction, as per bullion recovered, over a period of six months showed more than 100%, yet the work accomplished by these two plants was about on a par, and the widely different results shown were due to improper sampling-facilities in both instances, which could not at the time be remedied. I am always rather suspicious of an article which starts off something like this, after the introductory bow, '100 stamps ran 70,000 stamp-hours; stamp-duty, five tons per stamp; value of heads, $10; value of tailing, $1; extraction, 90%; fineness of bullion, 950; total cost of treatment, $2 per ton,' and so forth. Even figures thus glibly stated in an article generally indicate 'doctoring,' and I claim that anyone who publishes an article should be prepared to answer any question regarding it, and substantiate any statement contained therein.

I would also object to many articles which are written mainly to boom some special process or mechanical appliance. One or two such during the year might be all right, but when you get ten, twenty, or thirty treating of the same thing, it seems to be somewhat of an imposition on the reading public, and would look better to me in the advertising pages, or in a nicely bound catalogue. In regard to the manipulation of some of these modern appliances, one sees too often that the cost of renewals, repairs, and the like are insignificant. My limited experience has shown me that such 'insignificant' costs can generally be figured in cents per ton, so that in the belief that half a truth is little better than a lie, I would insist on explicitness. To carry out the above ideas would probably cause an enlargement of the editor's bump of discrimination to such an extent as to permanently disable him, but it would, in my humble opinion, improve the columns of many of our technical journals.

Rezongador.

Guanajuato, Mexico, August 10.

Mexican Mining Law.

The Editor:

Sir—in your leading article entitled 'Mexican Mining Law, published in your issue of August 1, you state: 'The Mexican regulation would preclude ownership of mining property by foreign corpora-
tions, and so do the statutes of the United States." On looking over "Skinner's Mining Manual" I find that many British companies are stated to own mining properties in the United States. The following are three well known English companies operating in different States, and said to own mining properties: Mountain Copper Co., Ltd., operating in California; Stratton's Independence, Ltd., operating in Colorado; and Montana Mining Co., Ltd., operating in Montana. The information contained in "Skinner's Manual" is supposed to be obtained officially from the companies and from Somerset House, London.

Which statement is correct? Do these foreign companies own any mining property in the United States or not? If not, what do they own?

R. Hay Anderson.

Mexico City, August 14.

[The statement made editorially in our issue of August 1, which our correspondent criticises, referred to the spirit of Federal legislation, which has been distinctly adverse to alien ownership, as manifested by the provision in the mining law which forbids a foreigner to patent a mining claim, and by the statute of 1887, which was amended in 1897 to read, "no alien or person who is not a citizen of the United States, or who has not declared his intention to become a citizen of the United States in the manner provided by law, shall acquire title to or own any land in any of the territories of the United States, except as hereinafter provided; provided that the prohibition of this section shall not apply to easies in which the right to hold or dispese of lands in the United States is secured by existing treaties to citizens or subjects of foreign countries, which rights, so far as they may exist by force of any such treaty, shall continue to exist so long as such treaties are in force, and no longer." The principle of State sovereignty necessitates jurisdiction over property rights, subject, of course, to treaties with foreign powers. Therefore, when a title has once issued the control over it by the Federal Government ceases and it is subject only to the laws of the State in which the property lies. For the most part, the several States admit aliens to buy and hold title to real estate without restriction. The Federal Government has, however, long proved itself sensitive as to foreign ownership of land.—Edron.]

Mining Claims on Forest Reserves.

The Editor:

Sir,—In your issue of August 8, in the editorial on "Mining Claims on Forest Reserves," the statement is made that the fee simple tenure of real estate has become strongly entrenched in this country. You have enjoyed a wide experience in Mexico, and probably other regions whose laws are inheritances from Spain. I am sure that I speak for a number of your readers in asking that you be kind enough to publish reasons that may be maintained against the adoption of such laws in this country. My understanding is that in Spanish America the title to mines or minerals beneath the surface is lodged in the commonwealth, patents of all descriptions being entirely restricted to the surface.

F. W. Carnahan.

Eileen, California, August 12.

Waters, Meteoric and Magmatic.

The Editor:

Sir,—The intensely interesting contributions of Messrs. Spurr, Winechell, Rickard, and Kemp, which have recently appeared in your columns, cannot fail to have caused many readers to compare occurrences which have come under their own notice with the theories advanced. On the one hand, it is hardly to be expected that all those in possession of pertinent data are qualified to express a definite opinion as to the importance of the facts as bearing upon either theory, and upon the other hand, it is probably next to impossible for those to whom the study of the subject is a special care, to formulate sets of conditions which would be acceptable to both sides as being positive evidence, one way or the other. I make the following suggestions with a view to assisting the crystallization of ideas from the magmatic stock of universal knowledge. Let all who are interested in the subject of the genesis of or bodies, out of the store of their own experience, cite one example, with all possible particulars of the conditions associated with the ore occurrence, which in their own opinion is the strongest argument absolutely known to them in favor of either or any theory, but without offering any deductions, each example to be headed simply 'Waters, Meteoric and Magmatic,' and signed. Let these examples be published in your columns. At the end of the specified time let the several examples be referred for criticism as to their bearing, to several authorities to be chosen by the MINING AND SCIENTIFIC PRESS, as representing as nearly as possible divergent views, and let the full response of such authorities be published. A stimulating discussion should follow and enlightenment would ensue.

Horace C. Nichols.

Ymir, British Columbia, July 10, 1908.

Smelting Charges on Goldfield Ores.

The Editor:

Sir,—In reading the article on Goldfield in your issue of July 11 it is stated that the smelter rates on ore assaying up to $50, were reduced to $6 per ton. I am anxious to learn whether the above rate of $6 covers all treatment charges, including insoluble contents; or is the insoluble, amounting to perhaps 60% or more, charged for at the rate of, say, 10c. per unit additional, making the total deduction $12 per ton for treatment charges.

E. Fleming L'Engle.

Los Angeles, California, July 15.

[The rate of $6 per ton covers the entire deduction made by the smelter, under the head of 'treatment charge.'—Edron.]

Asbestos is found in great abundance in the island of Cyprus, in the Mediterranean. It is reported that 1000 tons were mined during 1907.
DREDGING IN THE YUKON.

Written for the Mining and Scientific Press
By T. A. Richard.

Frozen ground is generally supposed to be a fatal obstacle to the profitable dredging of gold-bearing gravel; it is usually assumed that all the alluvium of the Far-North is in a perpetually frozen condition; in consequence, the opinion obtains even among well informed engineers that dredging in the Yukon is at best a costly experiment. The following data, recently gathered by personal observation, will be of interest to the profession and to others engaged in this branch of mining.

The first dredge to go to work in the Yukon was that of the Lewes River Mining & Dredging Co.* This machine was built to operate on the Cassiar bar of the Lewes river, a tributary of the Yukon, in 1899. In 1901 the dredge was moved to Claim No. 42 Below Discovery on Bonanza creek, and in 1903 up the creek to the Discovery group of claims. Last year the dredge was moved down to No. 6 and 7 Below Discovery, where it is now. On claim No. 42 the work was done on the basis of a 50% ‘lay,’ that is, the gross output was divided between the claim-holder and the dredging company, but in every other instance this dredge worked on ground belonging to its owners. This machine is now out of date, but it has given excellent service despite hard treatment. It was built by the Risdon Iron Works of San Francisco, and has 3 3/4 cu. ft. buckets, open-connected, giving a capacity of 900 cu. yd. per day. The screen is 4 1/2 ft. diam. and 17 ft. long. The stacker is of the Risdon type, that is, a bucket-conveyor, which the superintendent, Edward Simpson, says has not given a minute’s trouble. For a short stacker of small capacity such as this, the bucket-conveyor is well adapted. The digging-depth reaches to 20 ft., that is, a maximum depth below water of 18 ft. About 4 ft. of bed-rock is removed, up to a maximum of 6 ft., as determined by panning the material brought up by the buckets. The dredge is operated by steam power obtained by burning 3 cords of wood per day, or 83 cords per month. The season averages 160 days. The dredge at the time of my visit was extracting 100 oz. gold, at $15.50 per oz., per day, so that the yield must average $1.70 per cubic yard.

The lips of the buckets are made of tool-steel, oil-tempered, and every other bucket is provided with a tooth such as is attached to a steam-shovel. This tooth is effective in tearing the mica-schist bed-rock, and saves the lips from excessive wear. Quicksilver is used in arresting the gold, the quicksilver being fed to the tables at intervals of 3 hours. The clean-up takes place every 24 hours. Two 12-hr. days are set aside monthly for repairs.

The ground is thawed artificially ahead of the dredge. It has been ascertained that the ground will keep warm for a month, so it pays to keep the thawing at least that much ahead of the digging. In any part of the creek that has been previously worked, as by drifts, accumulations of ice are found, due to seepage of water into voids and the effect of the ground-ice. In gravel that has not been molested the conditions are more favorable, for there the seasonal thaw will conquer the frost, if once the covering of moss be removed. Mr. Simpson informed me that it is necessary to thaw artificially all the ground to be dredged, for an encounter with a pillar of ice will rack the dredge more than a month of ordinary work. “It is like putting the dredge against so much granite.” The thawing was in progress just in front of the dredge, the steam-points being distributed at intervals of 4 by 8 ft. As the season progresses the interval is increased; at first, in April, it was 4 by 4 ft., and this was widened until by June 20, it had become 8 ft. one way and 4 ft. the other. On July 17, the day of our visit, the seasonal thaw had softened the ground down to 7 ft., so that the points had that much less to do. The cost averages 12c. per cu. yd. In virgin ground an interval of 24 ft. for the points would be effective, but it does not pay to take chances wherever there are old workings, for the frozen pillars, topped by patches of moss, constitute the best of the gravel, and in old workings there is an agglomeration of gravel and ‘muck,’ with ice, making it imperative to thaw the whole mass. It is poor economy to take chances, for not only does the frozen ground imperil the dredge, but it prevents extraction of the gold. In virgin ground, after stripping the moss and mould, the natural thaw would reach to 14 ft. at the end of two seasons. This dredge has extracted about $700,000 in its various applications. By a life of seven years, that is, seven short seasons, and a probable further usefulness to the end of next summer, it has demonstrated what good service even one of the older and smaller machines will give under adverse conditions.

The Canadian Klondike Co. commenced work on the Boyle Concession three years ago, and began dredging in August 1905. This boat, built by the Marion Steam Shovel Co., has done most satisfactory work, considering that it was designed in 1904, since which date much has been learned concerning details of dredge construction. It is interesting to state that this dredge in the valley of the Klondike river is practically a counterpart of the ‘California No. 3,’ at Orville, operated by the Orville Dredging Co., although strengthened in parts, and with a better screen-arrangement. The record of the dredge on the Klondike is fully as good as that working under the supposedly more favorable conditions in California. In 1906, from May 9 to October 23, this dredge handled an average of 2935 cu. yd. per day; in 1907, from May 15 to October 9, this dredge dug 3490 cu. yd. per day. It is known that a good profit was made in both these seasons.

This dredge is the only one at work on the Boyle Concession, a tract covering 40 square miles, and extending for 6 1/4 miles along the Klondike, so as to cover from half a mile to one mile wide of alluvium. The gravel is 22 to 35 ft. deep, and bed-rock is soft schist, so that the buckets dig into it to

*At the present time there are 17 dredges at work in the Yukon Territory.
Dredge No. 6 of the Yukon Gold Company, on Bonanza Creek, Yukon Territory, Canada.

Dredge No. 6. Boiler Plant and Thawing Apparatus on Claim No. 90 Below Discovery, Bonanza Creek, Yukon Territory.
a depth of 4 ft. No artificial thawing-methods are employed, the ground having been softened by the successive seasonal thaws, following the removal of the overburden of moss by freshets sweeping across the flat valley. A little frozen ground was struck near the edge of the channel, without damage to the dredge, and without benefit to the clean-up; the buckets cut into it and excavated it successfully, but the fragments of frozen gravel were not disintegrated in the screen, passing onto the tailing-pile without the extraction of any gold that they might have contained. With the exception of this incident the frozen ground, which is such a bugaboo to dredge-masters in the North, has played no part in the record of this particular dredge.

It remains to add that the buckets are each of 7 cu. ft. capacity, close-connected, so that the machine handles 3900 to 4000 cu. yd. per day. Power is applied through the medium of electricity, generated by a 400-kw. Westinghouse generator, making 3600 revolutions per minute direct-connected to a Parsons’s steam-turbine. Wood at $7.75 per cord is burned in water-tube boilers, supplying steam at 165 lb. pressure. No quicksilver is used on the boat. The gold is arrested by riffles made of expanded metal stretched upon cocoa-nut matting, which in turn lies on canvas. This arrangement reaches for 44 in., and is followed by 8 ft. of angle-iron riffles, to which is added a tail-sluice with more riffles. Of the total extraction, 97% is effected the 4 ft. of expanded metal and matting. When a clean-up is to be made, the expanded metal is lifted, the matting is rolled in the canvas, to be carried to the clean-up room, at some distance from the dredge and near the office. Here the matting is washed in a tub, the residue is packed, and the gold collected for melting into bars, while the reject is fed into a grinding-pan to which quicksilver is added. The gold is coarse; after melting, it is 745 to 755 fine, and is worth $14.50 per oz., deducting the Government royalty, or export tax, of 37½c. per ounce. It may be mentioned that this dredge was started in ground which had been partly worked by an un-systematic combination of steam-shovel, dump-cars, washing-plant, and finally steam-scrapers to move the tailing, this complex operation resulting in a loss on gravel averaging $2 per cubic yard, while the dredge is reputed to have earned handsome profits in the same ground.

The Yukon Gold Co. will have seven dredges in operation before the close of the present season. The three dredges first built had buckets of 5 cu. ft. capacity. The four new dredges, of which two are completed, and two are nearly finished, have buckets of 7 cu. ft. capacity, and they have been designed to fit local conditions. On July 15 I visited one of these larger dredges, namely, that known as No. 6, on Bonanza creek, at 90 Below Discovery. All claims are numbered from the Discovery claim, up or down the creek. In the Yukon Territory each full claim extends for 500 ft.; the number multiplied by 500 gives roughly (for fractions intervening) the distance from the place where gold was first found on that particular creek. Dredge No. 6 of the Yukon Gold Co. is an up-to-date machine of the most approved design and built by the Bucyrus Co., of South Milwaukee. Going aboard the dredge, it is noted that the buckets have lugs designed to transmit the digging-stress from the lips to the base, and to relieve the rivets from excessive strain. Mr. E. E. McCarthy, the dredge superintendent, informed me that the lips of the buckets were made of Manard manganese steel, the base of chrome-nickel steel, and the hood of cast-steel. Each bucket has a capacity of 7 cu. ft., and as the speed over the tumbler is at the rate of 23 buckets per minute, the capacity of the dredge is from 90,000 to 125,000 cu. yd. per month, depending upon conditions. These conditions include, more particularly, the depth of the gravel, the character of the deposit, and the amount of bed-rock excavated.

The lower tumbler is circular, instead of having the more usual lugs or ears; it completely fills the space between the lower castings of the ladder, so as to prevent the crushing of gravel that might otherwise fall between the ladder and the tumbler. This tumbler has also a through tie-rod, which may be removed without removing the lower journals. The ladder itself is of most recent design, with a throughout-sluice arrangement; this takes all the spill from the buckets to the lower end of the ladder, discharging it into the pond for re-handling by the buckets. The rollers are made of chilled-iron and manganese-steel; they are of 14-in. diam., fitted with 3½-in. shaft and self-aligning bearings. The ladder has double suspension, which distributes the load. The bow-gantry is of 4-post trussed design, as shown in the accompanying photograph. By this design a portion of the strain created by the digging is transmitted to the outside of the hull near the center of pressure, thereby preventing the warping of the bow-pontoon. A new style of fair-lead sheaves on the bow lines is calculated to lessen the wear on the ropes when feeding across the cut. The ropes are of ¾-in. steel. The pair of main gear-wheels actuating the upper tumbler are 12 ft. diam. The tumbler-shaft is 16 in. within the tumbler and 14 in. within the driving wheel. All the gear of the upper tumbler-drive is cut-gear; the shafting is made exceptionally heavy, the intermediate shaft being 8 in. diam., so as to resist severe strains. Both the intermediate shaft and the tumbler-caps are securely anchored, in order to withstand the upward thrust.

The buckets discharge into a hopper having a bottom made of gravel resting at a natural angle, so that wear of iron is obviated. In the older designs the gravel fell down a chute, the lining of which had to be replaced at intervals. The revolving screen, which sizes the gravel so that the coarse goes over the end of the boat while the fine undergoes further treatment, is 6 ft. diam. and 28 ft. long; it weighs 6 tons and makes 9 revolutions per minute. The frame of the screen consists of castings and angle-irons, to which perforated plates of ¾-in. steel are fastened. The upper part of the screen has ¾-in. tapered holes, and the lower end has 1
by 2 in. slots. Angle-irons are placed within the screen, transversely, so as to impede the flow of gravel and cause thorough washing. When worn, the screen-plates can be patched. The periphery is subdivided into 6 pieces and the length of the screen into 5 divisions. The plates will wear for 8 months, the segments being interchanged so as to equalize wear. This result is also obtained by reversing the revolution of the apparatus during the next season. The screen has a slope of 1½ in. per foot. From the screen, the small gravel falls into a 'distributor,' so as to equalize the quantity of material descending upon each of the 14 tables on which the gold is arrested. This distributor may be described as a hopper-trough in step-like subdivisions, each of which has a door through which the gravel is admitted to the tables. By this arrangement it is possible to regulate the feed on each table.

A water-pipe traverses the screen lengthwise inside, to spray the gravel; and there is another pipe outside to supply the tables with additional water.

These tables, of which there are seven on each side, are wooden frames crossed by so-called 'Hungarian riffles,' these being merely strips of wood covered by ½ in. iron, 1½ in. wide. The iron tops slope in a direction opposed to the flow of the gravel, and overhang on the opposite side, so as to form an eddy. The distance between the riffles depends upon the grade: here it is 1½ in., with a grade of 1½ in. per foot. Cooea-nut matting and canvas are being tried under the uppermost riffles. The tables are 3 ft. wide and 16 ft. long. They discharge into sluices running lengthwise with the dredge, and extending over the stern.

The riffles are held in place by longitudinal strips and wedges. By knocking out the wedges, the riffles are removed and the sand shoveled into a box, from which it is fed through a bath of quicksilver and thence into a small box fitted with riffles and traps. The amalgam is restored in the usual way. Quicksilver is fed by hand to the head of each table. This is done by scattering the contents of a bottle containing 8 lb., the operation being performed by the man in charge of the clean-up apparatus. Gold is visible on the tables, and the addition of quicksilver is regulated thereby. As much as 50 lb. per day may be used. Three flasks are held on the boat for this purpose, each flask containing 76½ lb. The clean-up is made as often as the riffles become choked, usually at intervals of two days. In order to arrest gold in the spill from the buckets, a supplementary system of tables (called the 'save-all') is provided in the well of the dredge. It consists of a steel grating, similar to an 'under-current,' discharging into a series of zig-zag sluices, with riffles, supplied with extra water. The stacker consists of a trussed girdler carrying a Robins belt-conveyor, the belt being 34 in. wide, moving upon troughing-idlers made of three pieces, so as to give excellent service. The return idlers are in one piece.

The nominal horse-power consumed on the dredge is 260, but it varies up to 15% overload when operating under adverse conditions of digging, and when running smoothly the consumption of power is much less than the nominal. In default of meters, no exact measurements are available. For the digging, a type F Westinghouse 100 hp. variable-speed motor is used. The starboard winch, which operates the lines governing the movements of the dredge, is a type F 20 hp. variable-speed motor. The pumps are 10 in. and 8 in. Worthington make, under 50 and 35 ft. head, respectively, both direct-connected to a 75-hp. type CCL constant-speed motor. The screen is revolved by a 20-hp. motor of the same kind, through a counter-shaft to gears. The Robins conveyor on the stacker is operated by a 30-hp. motor, also of the CCL type. The CCL motors have proved less satisfactory than the older type C made by the same electrical company. Three transformers, of 100 kw. each, step the electric current down from 4000 to 440 volts. The transformers are on the boat itself and are so piped and connected that in case of fire the oil will escape under water; they are set in pans, with an outlet in the water.

The hull is strongly constructed, with two overhead trusses extending the whole length of the boat, which also has a transverse truss at the centre to take the heavy strains on the tumbler-gantry. The hull is 38½ ft. wide, 98 ft. long, and 9 ft. deep. The lumber came from Vancouver. The total weight of the boat is 800 tons. Most of the movements of the boat are controlled by one man stationed in the winch-room. The digging, or port-winch, is standard Bucyrus type, with Medart friction-clutches, specially made of cast-steel. The stacker is raised by an independent winch, which is actuated from the counter-shaft of the screen-drive. The screen, stacker, and pumps are not controlled from the winch-room. One man on deck looks after the oiling and running of the machinery. On shore, one man attends to the placing of anchors or 'dead-men' and the arrangement of the shore-lines. Two men are necessary for this work when the ground is shallow and the boat is advancing rapidly. Every part of the dredge is of the most approved construction, for the length of the season in the Yukon country is so short as to make experiments inadvisable. The choice of design is the outcome of wide experience in this branch of mining on the part of O. B. Perry, the general manager of the Yukon Gold Co., and it represents the best type of machine now at work in the North.

(The to be Continued.)

The world's mineral production for 1906 reached the stupendous quantity of 1,236,000,000 tons, according to the approximate figures now available, although the final statistics will probably show a greater amount. Of this almost unimaginable quantity, 1,100,000,000 tons was coal, which is an increase of 79,400,000 tons over the previous year. To this increase the United States contributed the largest amount (21,000,000 tons), with Germany a close second, and Great Britain third. The United States produced during 1906 more than 413,000,000 tons of coal, being at the rate of over 1,000,000 tons per day for the year. The value of the world's coal production was more than four times that of all gold mined.

temperatures 65 gm. of the mixture with 130 c.c. of a solution of sodium cyanide 0.25% strength (expressed in terms of KCy) in 800 c.c. closed vessels for six hours, together with the percentage stated in the table on the weight of the ore of the re-agents mentioned. The time of treatment was purposely limited so as to exhibit the difference in rate of dissolving, as otherwise given sufficient time the less favorable treatment might equal the more favorable in the final result. The mixed and diluted ore thus experimented on had a value of 9.2 dwt. gold per 2000-lb. ton, equal to 15.8 gm. per metric ton, and 277 dwt. silver per 2000-lb. ton, equal to 475 gm. per metric ton. In (e) 0.5% solution was used, of which nearly half had been converted into HCY by titration with HCl beforehand. In (h) and (j) the lead salt had been dissolved in a minimum of caustic soda before being added to the ore. After agitation in each case had been completed, the solution was at once filtered off, and the calculations are based on its gold and silver content, rather than on the residue, which might have decreased in value during the aeration consequent on thorough washing. Considerable free cyanide was present in the solution after treatment in each instance. The accompanying tables show the results.

In studying these it at once becomes apparent that the per centage extraction of the gold is usually better than that of the silver, but that a satisfactory gold result by no means implies an equally good silver extraction. In other words the same factors affect the two metals differently. In general, the chief influence favoring ready solution of the gold is oxygen in some form, and the results are better according as this element is amply provided, or worse as substances are formed which consume it. The two highest extractions (see a and b) are due to the oxidizer BaO, or to compressed oxygen. Variation in temperature (see c and d) shows little difference, possibly due to the alkaline CaO in the warmer solution dissolving more oxygen, absorbing sulphides, and thus counteracting any tendency of the gold to dissolve faster. The presence of HCY (see e) gives somewhat poorer results, which may be attributed to the presence of some gold alloyed with silver in the ore, and the slow rate of dissolving of the silver, retarding the solution of the gold. The trials with lead salts all show poorer results than the foregoing. PbO, with caustic soda is worse than without (see h and f), and similarly in the case of PbO (see j and t). This may be attributed to the caustic alkali dissolving and reducing sulphides from the ore. The available oxygen in PbO causes, however, better results than the use of PbO without lime (g), lead (h) that the PbS which formed absorb oxygen more readily than a corresponding amount of NaS in solution. The dissolution of silver is not only more imperfect than that of the gold, but is also more readily affected by varying factors. While accelerated by warmth and oxidizers, it is retarded, on the grounds detailed in the paper, both by the presence of soluble sulphides, and even more of hydrocyanic acid. The last is strikingly evident in the two lowest results (see g and e), where HCY is present in the solution, either through the addition of HCl beforehand, or through the effect of latent acid in the ore in the absence of protective alkali. While aurcyanhydride acid (HAuCry) is relatively soluble, I am not aware that the corresponding silver compound exists at all. Hence the presence of some
alkali appears advisable, and in any case its injurious effect is not so apparent as with gold.

The above results do not exhibit the benefit from the use of lead salts which might be anticipated from theory, so far as it is developed, and from their common use in Mexican practice. The reason is obscure, although the amount of lead salt used was much less than the sulphur-equivalent in the ore, and it is possible that some unrecognized feature of the ore experimented on, or of the tests employed, differed materially from usual working conditions. It is possible that the development of the use of warm cyanide solutions in South Africa, recently discussed in reference to accelerated slime-settlement by A. Salkinson, may be advantageously paralleled in silver ore treatment in Mexico, although the extensive use of electric power there does not provide a cheap source of heat in the shape of exhaust-steam.

To carry the effect of heat to an extreme, some of the same fine-crushed ore was boiled with twice its weight of 0.26% cyanide solution and 0.1% lime for six hours in an open beaker, water being added periodically to maintain a constant volume. This resulted in 90% of the free cyanide being decomposed, and only 28.3% of the gold and 32.6% of the silver being dissolved.

The foregoing experiments, however, leave much to be elucidated in reference to the precise influence, especially upon silver extraction under working conditions, of the following factors: (a) time of treatment, (b) temperature, (c) strength and volume of solution, (d) oxidizing agents and aeration by agitation, (e) lead salts, (f) presence of free alkali, or hydrocyanic acid, and (g) re-precipitation of the gold and silver. While in Mexico the mechanical features of fine-crushing, agitation, and filtering of slime have been skillfully and profitably developed, the actual percentage-recovery by cyaniding, and its cost, still afford scope for improvement, and there is little doubt that intelligent and systematic research from a chemical standpoint along the above lines would be as well repaid as it would be full of interest. In concluding this reply I may confess that the tentative views and speculations therein advanced are necessarily based on experiments upon material which was unfortunately limited in amount, and without the great advantage of constant contact and long acquaintance with working-conditions and observations. Moreover, in the vast mining area of Mexico, so diverse and complex are the ores, that generalizations are much restricted, and special conditions and problems have to be dealt with in each district and plant. Hence, while those with greater knowledge of the subject will doubtless properly dissent from some of the views expressed, I trust that a sufficient residuum of correct deductions may remain to justify this addition to the small amount of published literature upon the subject.

Babbitt metal was invented by Isaac Babbitt, in 1839, at Taunton, Massachusetts.

**METAMORPHIC RANGES IN SONORA, MEXICO.**

Written for the MINING AND SCIENTIFIC PRESS

By F. J. H. MERRILL.

While the mountains of Sonora, as a rule, consist wholly or in part of volcanic rocks, there are some metamorphic ranges which present a special type of mineralization, and deserve a brief description. Two observed by me are in the northern part of the State. One, on the boundary between Urés and Altar, about fifteen miles west of Puerto Station, is known as the Sierra del Maíz and consists of semi-crystalline limestone and mica schist. These altered sedimentaries are heavily injected with igneous rock in the form of dikes and bosses. Rhyolites and andesites are most prominent among these, but a coarsely crystalline rock, having the appearance of a diorite also occurs in small domes and bosses. This range has a length of twelve or fifteen miles, and separates part of the watershed of the Sonora river from that of the Magdalena. Another metamorphic range, called the Sierra Jojova, lies west of the Magdalena river and extends from the latitude of the city of Magdalena some thirty miles northward, till it unites with the range known as the Sierra Guacomea. The Jojova range is composed mainly of a very fine-grained mica schist, which, under the stress of mountain-making forces, has been extensively shattered by joints which traverse it in many directions. This schist is everywhere cut by pegmatite dikes, varying from 6 in. to 3 or 4 ft. in width and extending for considerable distances.

The metallization of this metamorphic range is not abundant, and, where I have made a study of it, is wholly in the form of impregnated or metallized shear-zones. A prominent example is that of the Sonora Bonanza, a mining property about four miles west of Imuris. There, in a shear-zone extending over a mile in length, is an orebody containing gold, silver, copper, and molybdenum, the latter in the form of wulfenite. A noteworthy circumstance is the occurrence, at a few points on the shear-zone, of sufficient quartz to give the semblance of a true vein-outcrop. Development shows, however, that these quartz masses are local deposits, and do not represent a continuous vein, although there is ore in the shear-zone below the quartz.

On the west side of this range near the Babinioqui ranch, are some small copper prospects. Here pegmatite dikes have been shattered along their length by shear-zones, and the fragments saturated with copper minerals, now altered to silicate and carbonate. Another mine in this range is the Jojova, which I have not yet been able to visit. Cerro de Plata is the name of still another mine to the northward. The northeastward continuation of this range is known by the name of Sierra Guacomea and contains some mining properties, but I have not yet had an opportunity to study its geology or its metallization.

Australia produced 3,180,940 fine ounces of gold during 1907, having a value of £13,511,766. During the same year the mines of the Transvaal produced 6,451,384 ounces, valued at £27,403,738.
MINERAL PROSPECTS AROUND DEATH VALLEY.

Written for the MINING AND SCIENTIFIC PRESS
By Robert E. Rinchart.

Mining activity in the vicinity of Death Valley, which in the heyday of the Greenwater and Skidoo excitements was booming, has sunk back to the dead-level of the lonesome days following the farewell of the twenty-mile borax teams. The inhospitable region is practically abandoned to chuck-a-walla, sidewinders, and a few burro-men camping about the canyon springs and desert wells. The panic of October bore down on Death Valley and cast a gloom that has not lifted. There is not a 'wild-eat' mewing loud enough to be heard above the desert stillness. Veterans living on the scant bounty of grub-stakers are reduced to half-rations or are going to work at the Lila Co., the prize mine of the Pacific Coast Borax Co. Nothing can do justice to the depression except the dirge of the lone store-keeper at Stove Pipe Well. This collapse of Death Valley mining would not be worthy of much consideration did it not mark the exhaustion of the most fertile field in America for mining fairy-tales. For a good half-century the mysterious hidden riches of Death Valley have been used to lure grub-stakes from men easy with their money. In more recent years they have been the capital of many a million-dollar capitalization. Has anyone ever attempted to compute the money spent in the quest of the rich silver lode of Bennett's Gunsight Lead or the wonderful gold butte of crazy Breyfogle? If he has, let him write it down to the debit side of Death Valley's account. Rash desert rats used to find even the Peg Leg mine as far north as Death Valley and dispose of it to simple strangers from the settlements. The region has been a bonanza for desert tramps. But the valley's age of mystery has come to a close. With motor cars honking across the salt-marsh and the Tonopah & Tidewater Railroad on its fringe, Death Valley has shut the book of its romance and is now looking forward to actual operation in mining.

What the region will amount to in future is largely a matter of conjecture. Some regard the surrounding mountains as a land of promise; others consider prospecting in the Panamint and Funeral ranges as a waste of time. Many old prospectors assert that the hills have been 'raked for ledges with a fine-tooth comb', while others are equally certain that the ground has no more than been scratched over. This much, however, can be taken as sure—the days of fake mining are gone.

From the time when pioneer desert-men came into the valley hunting the Gunsight Lead, until the discovery of Tonopah, the Panamints have been alive with prospectors. Plenty of water is found on the Telescope side of the valley in most any canyon. Snow stays the year round in the gullies of Telescope peak, yielding excellent drinking water to the
foothills below. Consequently the locality has always swarmed with 'desert-rats.' Moreover, during the years of the rush caused by the discovery at Surprise canyon, and for many years after, the Panamints came in for careful scrutiny. Funeral range likewise, as far up as the Grapevines, has been thoroughly ransacked. This range contains many borax deposits. In fact, it is the field from which the Pacific Coast Borax Co. plans to draw its supplies in future. Practically all the mounds and foothills of Furnace Creek 'wash' are now the property of that company. To secure these borax deposits the company for the last twenty years has had experts scouring Funeral range. Its hills have been tramped over by every sort of prospector. It is pretty good reasoning to infer that, were there any gold, silver, or copper deposits worth while in Funeral range, these scouts would have encountered some of them. As a matter of fact, the Pacific Coast Borax Co. does not own a gold, silver, or copper property anywhere in the vicinity of Death Valley.

This criticism does not hold good of the north end of Death Valley, which is sometimes variously called 'Johnny-behind-the-Gat,' which is short for 'Johnny-behind-the-Gatling-gun,' a sobriquet bestowed out of respect for the prospector's Mauser automatic combination pistol and carbine. Seity prospects. After he has been over a hill and left it, one can with easy conscience pass that hill. When necessary to examine a ledge the little Austrian will go up a canyon wall which any mountain sheep with an ounce of caution would avoid. As a result, Johnny has made three good strikes in his life, a fine record for any prospector's career. His last discovery was the Big Belle, a property in the Grapevines, which looks rich. Johnny has been 'promoted' entirely out of the Big Belle. For that reason he is down in the Panamints looking for another. His presence is considered a good recommendation for the Panamints as prospecting ground.

Death Valley has one actual mine with which to begin its new era. It is the Keane Wonder, a wonder if for no other reason that that is the only producing property of the region. While not a bonanza, it is paying. Forty miners are busy supplying $20 ore for a 20-stamp mill. Now and then a gold bar finds its way to Rhyolite, and figures in the press dispatches. Skidoo, on the west slope of the Panamints, disputes the Death Valley’s supremacy. From Bob Montgomery’s camp come reports of forty miners delving into ‘picture-value’ ore. Skidoo’s mill of 10 stamps is completed and at work. The monthly output is said to be $10,000. Skidoo insists that it is part of and parcel of Death Valley, though it more properly belongs to the Panamint valley.

Not far from Saratoga Springs, at the extremity of the south arm of Death Valley, the bustling little supply-camp of Silver Lake is kept alive by a large mining district that extends from the Shadow mountains on the east to the Avawatz on the west. Greenwater is still trying to keep itself from utter collapse. Following the New Year, when rumor had it that Panamint Tom, an ancient Shoshone warrior, with his squaw, was hibernating on the Greenwater bank, a force of men, about a half a dozen miners, went to work in the copper properties. Occasionally the long-silent telephone wires to Rhyolite dropped whisperings of fancy ‘strikes’ at Greenwater. These found their way into print, but Greenwater failed to sustain the promise of its earliest boom days for anyone to take much interest in these later murmurs.

Scotty’s Death Valley mine has moved up into the Tin mountains. This mine, of the ilk of Peg Leg and Breyfogle, when it sprang into the lime-light, was down at the lower end of the Panamints, near Hidden Spring. Since then it has zig-zagged back and forth across the valley in a northern flight. First it skipped to Funeral range; next to the Panamints near Emigrant Spring. Later it sifted over to the Grapevines and rested till the work of the Keane Wonder made the district too busy. Now it has taken refuge in the isolation of the Tin mountains, probably for the reason that last spring four human skeletons and the bones of six burros, grim relics of a prospecting party, were found in a Tin mountain canyon.

The Borax company has planned an unusually
large amount of assessment work for this fall on its Death Valley properties. It is probable that 50 or more miners will be taken over to Furnace Creek canyon. Each year's work adds thousands of tons of colemanite to the already immeasurable Death Valley store. Meanwhile the Lila C. mine is turning out sufficient borax to supply the American market. Since the transfer of operations from Borate to the new borax camp, Ryan, which is named after John Ryan, who for years has been the company's field representative, the company has kept more than a hundred miners following the extensive colemanite veins of the Lila C. The roster, begun last spring, is now completed and running with a good force of men. The cabins and bunk-houses have been moved to Ryan from Borate. The Tonopah & Tidewater railroad has opened up the territory east of Death Valley. This region in three years has become quite well known. The soda lake, on the Mojave desert, near the ruined fort on the overland trail, which was once worked for its soda, is receiving the attention of two groups of capitalists, now that a railroad touches its very edge. Along the walls of Amargosa canyon nitrate beds have been discovered. They are low-grade deposits. Nevertheless, they look promising enough for someone—rumor says it is the Borax company—to take up the ground and do considerable assessment work. Death Valley's final contribution to the world's wealth seems more likely to come from such minerals as borax and salt than from precious metals.

Suitable refined oils may be determined by the following simple tests, according to J. C. Christensen in the June issue of California Derrick: Gasoline should burn with a blue flame in the usual form of burner. If it does not, too much 'heavy oil' is present. Benzine which is used for cleaning clothes should evaporate from a fabric within a reasonable time, leaving no pronounced odor on the goods. Turpentine substitutes should evaporate from a piece of white paper in less than 45 minutes, leaving no grease spot. Kerosene need be tested only for flashpoint, sulphur, and burning qualities. Kerosene is supposed to be burned in a lamp. If it will not burn, the fact can be ascertained only by trial; and if it will burn, what is the use of further tests? The reason why an oil will not burn may be very difficult to ascertain, and may involve years of chemical research. Borneo oil, it is said, will not burn in flat-wicked lamps, but will burn well in lamps with a central draught. California oils, if improperly refined, behave in the opposite manner. Viscosity is the prime requisite of a lubricant. If the oil has the proper viscosity, it is free from acids, alkalis, and gum-forming bodies, it will undoubtedly give satisfaction. Here also if an oil is unsatisfactory, the reason and remedy may be very hard to discover.

Oil-burning boilers are to be used on ten new torpedo-boat destroyers for the British Navy. Burners which do not require the use of steam or compressed air for atomization will be used, consequently the oil will be put under pressure and heated to the flash-point before passing to the burners.

**ROCK PRESSURE AND METAMORPHISM.**

Written for the Mining and Scientific Press By H. M. Chance.

While in many contributions to the literature of metamorphism, rock pressure is treated as an important factor in changing the arrangement of the mineral constituents of rock masses, in indurating, in dehydrating, and in welding the loose agglomerates into cohesive rocks, the subject does not seem to have received the attention nor to have been given the prominence that its importance merits; nor has the possible presence of enormous stresses in any or all parts of the lithosphere been sufficiently emphasized. These stresses are limited only by the ultimate strength of the rock-masses in which they develop, and to the pressure under which rocks may flow as liquid or plastic bodies, and may exist not only at great depth, but also in rock-masses at or immediately beneath the surface. What may be termed lithostatic pressure, that is, the pressure due to the weight of the overlying strata, may be computed approximately at one pound per square inch for each foot in depth. For example, this pressure at a depth of 2000 ft. beneath the surface is about 2000 lb. per square inch, and in like ratio for other depths. As shown by me several years ago, this lithostatic pressure limits the possible underground pressure of gases, for when the gas pressure exceeds the lithostatic pressure, the formations will be lifted and broken and the gases escape.

If this were the sole compressive stress to which the rocks are subjected, no considerable metamorphism by 'welding,' that is, cementation or induration, would be expected to result from this cause except at depths of many thousands of feet, perhaps 20,000 to 50,000 or more, below the surface. The pressure due to thrust may, however, enormously exceed the lithostatic pressure, and these thrust-stresses may be very great at slight depths beneath the surface, or indeed quite near the surface. The possible stress due to thrust may best be conceived and calculated by imagining the earth's crust to consist of a series of concentric and unsupported rock rings, domes, or zones. If the stresses in such rings be computed by treating each ring as an arch, it will be found that the stresses are greatest in the outside, superficial ring, steadily diminishing toward the centre, and that in the outside ring the compressive stress is approximately 20,000,000 lb. per square inch, this being the pressure, or thrust, developed in an arch of 4000 miles radius and constructed of material having the average weight per cubic foot of ordinary sandstone. It cannot, however, be assumed that such pressures actually exist for even a limited time or throughout a circumseribed rock-mass, for the underlying rocks must always afford some support to portions of any rock-shell which may become partly suspended, and also because the arched formations will break by crushing long before the pressure produces such an enormous compressive strain.

It is, however, unquestionable that these thrust-stresses are very great, and are sufficient to account for many of the phenomena usually ascribed to
cementation by silicification, for whenever, through any cause, the sinking of the underlying rocks has for a time left any portion of the lithosphere unsupported except by its own strength as an arch, enormous pressures are produced; the resultant of the forces involved tending to produce stresses far beyond the ultimate strength of any known substance, and the effect of which it may be difficult to surmise. An objection to this argument may be made on the ground that subsidence of underlying rocks accompanied by unsupported arching of an overlying belt or ring will seldom occur, and therefore that such stresses will rarely be produced, and with this contention I am in thorough agreement, having introduced the foregoing hypothesis to illustrate how such stresses might arise, and how they may be estimated. The real condition differs from this simple conception, and requires the introduction of another physical factor, namely, the elasticity of rocks. All rocks are more or less elastic and correspondingly compressible, and, under the compressive force of the lithostatic pressure, or absolute weight, they yield, occupying less space, that is, decreasing in bulk. The effect of this compression is, in a measure, the same as though the underlying rock-mass had subsided, and no longer sustained the whole weight of the overlying strata, which must then act as an arch, as regards such unsupported weight, developing enormous thrust-stresses, or must break and settle upon the underlying rock-mass.

Compressive stresses existing in rocks at the surface have been noted by a number of observers, being mentioned by Van Hise and others as showing sufficient stress to produce a measurable compression even in granite. An instance is cited by Van Hise in which granite blocks visibly expanded after being detached or cut loose from the main rock-mass in ordinary quarrying operations. More striking instances are found in the 'swelling ground' of some mines, where the stresses are sufficient to shear off massive rocks, closing drifts and cross-cuts driven in solid and undisturbed ground. Hence it seems reasonable to assume that the 'thrust of the arch' underground, and also close to the surface, produces pressures limited only by the ultimate strength of the rocks, and that the resultant stresses are sufficient to account, (1) for the cementation by 'welding' of loose and non-cohesive materials, such as fragmental and volcanic sediments and deposits, into cohesive rocks; (2) for the fracturing which has produced the brecias; (3) and for the development of cleavage (schistosity) and joint-planes.

From purely mathematical considerations it is evident that thrust-stresses developed by the arching of any rock-mass, whether from the actual uplifting of the mass, due to the subsiding of the underlying rocks, or from the compression of such underlying rocks due to their elasticity, must bear a definite relation to the radius of the arch so formed, being greater when this radius is large and less when the radius is relatively small; and further, that all lateral thrust-stresses, other than those produced by igneous eruptive pressures, must in their final analysis be attributed to this cause. To distinguish these stresses from those produced by igneous eruptions, and also from the lithostatic pressure, the term arch-thrust is suggested. Arch-thrust stresses are produced artificially in mining and are doubtless an important factor in bringing on 'crushes' or 'squeezes.' In view of the disasters caused by the crushing of coal pillars by the development of 'squeezes' it is remarkable that few engineers have directed attention to the fact that many mine-closures are caused by the 'thrust of the arch.' In these cases the development of a thrust many times that of the weight of the overlying strata, is brought about by the partial removal of support from beneath a considerable area, pillars of coal amply sufficient to sustain the weight of the overlying mass being crushed to powder by the thrust. Conditions which give rise to the development of arch-thrust stresses will rarely affect all parts of any formation uniformly, for while some parts of the formation may be subjected to destructive stresses, other portions may, by reason of faulting, or by reason of being within a zone in which the resolution of forces produces less thrust, be subjected to pressure no greater than the local lithostatic pressure, and may thus escape the metamorphic changes produced by the greater pressures. In other words, metamorphism by arch-thrust stresses, differs from that produced by lithostatic pressure, in that it may vary locally and without reference to depth, whereas metamorphism due to lithostatic pressure should be uniform for any given depth, and should vary with the depth. Metamorphism by arch-thrust stresses furnishes an explanation of the variations observed in cementation of the sedimentaries, especially of the sandstones and grits, which in some localities may be completely cemented, in fact almost converted into quartzites, while at other places near by they may retain the loose-grained, porous structure of slightly cemented sand-beds. It thus becomes evident that enormous pressure and stresses must continually be present in portions of the superficial as well as in the deeply buried portions of the lithosphere; that these stresses are due to arch-thrust and may readily account for cementation by 'welding,' brecciation, faulting, and the development of cleavage (schistosity), and joint-planes, near or at the surface as well as at considerable depths; and further, that the phenomena of rock-flow under pressure, dehydration, distortion of bedding, and of structure, the development of crystalline rock-structure and the transposition or rearrangement of the mineral constituents of rock-masses are not necessarily confined to deeply buried rocks, but may also occur at or near the surface. If this be true, it is no longer necessary to ascribe cementation to silicification or silicification upon a gigantic scale, involving the removal from rocks near the surface and the reprecipitation in the deeply buried formations of vast quantities of silica; nor is the presence of water essential to cementing or indurating processes which are brought about by arch-thrust stresses. On the contrary, such cementation and induration would seem more likely to become complete in partly dehydrated materials, or at least in materials from
which the surplus water had been squeezed out of the pores. Possibly such pressures acting in moderately elevated temperatures will more rapidly bring about complete cementation than at lower temperatures, and if the temperature be high enough to drive off most of the combined water, more complete metamorphism, and the production of highly crystalline rock-masses, with re-arrangement or re-crystallization of minerals, may be more likely to result; but it does not seem necessary to assume high temperatures to bring about those changes, for pressure, time, and chemical activity are probably competent to effect profound changes in the physical and chemical constitution of rocks.

This hypothesis appears to furnish a more plausible and rational explanation of many phenomena of metamorphism than that which assigns to percolating and circulating waters the principal role in bringing about such changes. I have in mind more particularly the phenomena observed in the sedimentaries, but believe the same considerations will apply with equal force to changes in rocks of igneous origin. Those who have given much attention to the study of the sedimentaries will be slow to admit any general, and especially and vertical circulation of ground-waters which would account for cementation by the transportation and precipitation of silica sufficient in quantity to fill the interstices of the more porous sedimentaries. The theory is met at the outset by the objection that surface-waters rarely penetrate to any considerable depth; that deep mines are usually dry mines, and that deep bore-holes are usually dry holes, and that the dryness of the underground is actual, not relative, that is, that deep mines are not only dry, but often are dusty. The exceptions are of course found in mines opened on fissure veins and in bore-holes sunk in artesian districts; but these exceptions merely emphasize the rule. Again, the history of drilling in sedimentaries shows that after passing below the surface-water horizon, which rarely extends to more than a few hundred feet in depth, either the rocks are dry, or they contain salt water, that is, brine, and the brine is frequently quite pure. Where such conditions exist, it is evident that silica is not continuously being carried in solution from the superficial to the deeply-buried formations. The existence of large areas underlain by shales, slates, and sandstones permeated with oil and gas, prevents the application of this theory to the cementation of rocks in such districts.

The application of such theories to cementation and also to the formation of ore deposits by precipitation, requires that precipitation shall take place, but without in the first case furnishing a valid reason for such action. Precipitation involves either the addition of some reagent by which the substance is thrown out of solution, that the solution be a concentrated solution, that the specific gravity of the solution be changed by the addition or removal of water, that its temperature or pressure be changed, or that it be subjected to electrolysis. If the almost universal cementation of sedimentary rocks be due to the addition of silica brought in by circulating waters, then we should be able to furnish a plausible reason why these waters should deposit this silica in the interstices, removing nothing, that is, dissolving no part of the rock-mass. In applying any theory of carriage by circulating waters to the formation of ore deposits, the same difficulty is experienced, but precipitation can plausibly be explained by assuming that the mineralized waters commingle with other waters carrying a precipitating reagent, or that they react upon the rock-mass in which the metalliferous precipitate is being deposited.

Cementation by the deposition of small quantities of silica or silicates, barely sufficient to cement the individual sand-grains, may not improbably be brought about in the entire absence of circulation by dead waters occupying the pores of any unsolidified material, for this water may dissolve small quantities of silica from the sand grains and re-deposit it upon them, the water remaining practically a concentrated solution of silica or silicates throughout the process. This affords an explanation of the cementation of sand-beds lying in unsolidified sedimentaries at depths beneath the surface too shallow to permit of cementation by 'welding,' for at a shallow depth lithostatic pressure is insufficient for the purpose, and in entirely unsolidified and unconfined surface-sedimentaries arch-thrust stresses must be a small and unimportant factor. The application of this arch-thrust theory is restricted to cemented or solidified, and to partly cemented, solidified, or slightly indurated materials, requiring that before the development of arch-thrust stresses, lithostatic pressure or chemical solution and precipitation or possibly cementing by re-arrangement, shall have converted the non-cohesive materials into partly solidified deposits, or that cementation by precipitation of calcareous or silicious matter, or silica, as described by Van Hise, shall have performed the same function; for no arch-thrust stresses much exceeding the lithostatic pressure can develop in loose and unconfined materials. In applying this reasoning to rocks within the zone capable of observation, it becomes necessary to consider the conditions under which the phenomena of rock-flowage and the development of crystalline structure are possible. Experimentation has not progressed far enough to define the pressures which will develop either flowage or crystalline structures in large rock-masses, and the results so far attained do not harmonize very well with the conclusions reached from observation.

Rocks are exposed in many localities which have been buried beneath 20,000 or 30,000 ft. of superincumbent strata, and yet exhibit no well-developed evidence of flowage or of crystalline structure, although the pressures to which they have been subjected have been not less than 20,000 to 30,000 lb. per square inch. While the experiments of Adams, Nicolson, and others indicate that deformation and re-arrangement commence at much lower pressures, many experiments involving pressures greatly in excess of 100,000 lb. per square inch have entirely failed to produce any effect other than that of crushing the rock to powder. The data in hand

Decisions Relating to Mining.

Specially reported for the MINING AND SCIENTIFIC PRESS.

Breach of Contract—Substitute for Damages.

A contract for the sale of a mining claim provided that on non-compliance with any of its terms the purchaser should forfeit all machinery and appliances placed on such claims, and that such forfeiture should be in full liquidation of all claims and demands. This was held to provide for the measure of damages for the breach of the contract, to the exclusion of a remedy by cancellation of the contract of sale, or specific performance.

Mallory v. Globe Boston Copper Mining Co. (Arkt.), 94 Pac. 1116, March, '08.

Notice of Location of Mining Claims.

Notices of the location of mining claims were sufficient where they contained such a description of the locality of the claim by reference to natural landmarks or permanent objects as to render the situation of the same reasonably certain from the letter of the notice itself.

Location of Mining Claim—Natural Objects.

The purpose of the law in requiring the location of mining claims to be made with reference to some natural object or permanent monument is said to be for the purpose of directing attention in a general way to the vicinity or locality in which such mining claims were to be found; but the natural objects or permanent monuments required may be either on or off the ground located.

A contract for the sale of mining claims which provided that the purchaser should run certain cross-cuts, shafts, and drifts, will not be specifically enforced where there is no time specified in the agreement when the work should be done, and where there was no allegation that the plaintiffs had been damaged by the failure to perform such particular acts.

Mallory v. Globe Boston Copper Mining Co. (Arkt.), 94 Pac. 1116, March, '08.

Reservation of Minerals in Conveyance Land.

A general reservation of all minerals 'in and under' a certain portion of land conveyed, not limited or qualified by any other clause in the deed, or by any facts within the knowledge of the parties which might properly be deemed to have influenced them, was held to include not only sold minerals, such as gold, silver, iron, coal, etc., but also natural gas and oil.

Mining Property—Partition.

Ordinarily mining property is not susceptible of partition, and the usual practice is for a court to order the property sold and the proceeds divided. But it seems that under the statutes of Alaska a division of the property must be made; and the court shall appoint three referees to make the division and allot the several interests. Personal property connected with such mining property must be dealt with in the same manner, and could not be sold by a receiver appointed by the court.

Mining Claim—Re-Location.

There can be no re-location of a mining claim while it is in the actual possession of persons who have done the requisite amount of assessment work, although under an insufficient location. The rule is that for the purpose of re-location, the land must be open and subject to location.

Ware v. White, (Ark.) 108 Southwest 831, Jan., '08.
MINING AND METALLURGICAL PATENTS.
Specially reported for the MINING AND SCIENTIFIC PRESS.

A concentrator for ore and other materials, comprising an elongated trough-like vessel, the major portion of whose bottom is provided with closely adjacent small holes or perforations therethrough, a water compartment below said bottom, from which water under pressure is admitted through said perforations, and means for mechanically moving the ore or other material longitudinally in one direction in the vessel and for permitting the water to carry off in suspension the gangue and other material in the opposite direction.

CRUSHER FOR ORE AND OTHER MATERIALS.—No. 893,713. Henry Esgers, Denver, Colorado.

In an ore and rock crusher, the combination with the main frame, of the crusher frame, having a stationary jaw; an oscillating jaw arranged in operative relation to said stationary jaw, a recess in said swinging jaw, a pin jour-naled in said recess, a pair of tie bars positioned one on each side of said frame, provided with eyes at one end fitting loosely over the opposite ends of said pins, and having their opposite ends threaded, an abutment bearing adjacent to said stationary jaw in said crusher frame, a rotatable tie bars loosen-leng and tightening eccentric abutment sleeve mounted in said abutment bearing, and provided with an open slot portion in its side, a link in said side slot extending across said frame, eye portions on the opposite ends of said link fitting loosely over the threaded end portions of said tie rods, and a handled nut threaded to the threaded ends of each rod and arranged to screw against the eye portions of said link and clamp it and its eccentric sleeve to the abutment bearing of said frame, and means including a handle connected to said eccentric sleeve for rotating it to instantly loosen said tie rode and release said jaw from its set positions relative to said fixed jaw.

In a cutter-head, the combination with a frame compris-ing side plates, one of which is provided with an opening having an inwardly beveled wall and the other of which is provided with a threaded opening, of a bolt disposed trans-versely in the frame and threaded oppositely to the threaded opening in one flame plate and having a cap or head occupying the opening in the other flame plate and having its edge beveled correspondingly to the wall of the latter opening, an exteriorly threaded disk arranged in the threaded opening of the flame plate and having a threaded aperture receiving the threaded bolt, an interiorly threaded journal mounted on the threaded bolt and disposed between the flame plates, a wheel surrounding the said journal, and a cutter chain passed over the wheel.

In a crushing machine a mortar, a crushing head within the mortar, a shaft carrying the head and extending below the lower end of the mortar, means engaging the upper ends of the shaft for imparting a gyra-tory movement to the shaft and head, means to hold the shaft against downward movement, and means intermediate the lower extremity of the shaft and the head for providing a lateral resistance against the movement of the shaft.

The process of separating ore slimes from crushed ore or gangue and recovering the slime, which consists in intro-ducing the crushed ore or gangue containing the slime into a receptacle, subjecting the material therein to the action of the water, whereby the slime will be separated from the crushed ore or gangue and will flow out over the edge of the receptacle with the water, the slime by the addition of washing water being greatly diluted, conveying the water carrying the slime in suspension into a receptacle, and uni-formly heating the same throughout without boiling, agitat-ing or boiling currents in the water containing the slime, whereby the slime is caused to precipitate without disturb-ance, and then drawing off the water from from slime from the receptacle.
First-Aid in Accidents.

The greatest danger to wounds from accidents is due to contamination with foreign substances, not always visible but far-reaching in effect. Germs quickly find lodgment in any wound by transference from the air, the clothing, the skin; in fact, from anything that may come in contact with it. In consequence of such contamination, blood poisoning, gangrene, inflammation, fever, erysipelas, and a train of complications are liable to follow any wound. Small scratches and pricks, when not properly cared for, may result in inflammation and the formation of gathering or abscesses, which will disable a person for a considerable time or cause the loss of a limb, or even endanger life itself. A knowledge of these facts has led to the triumphant progress of modern surgery. The application of the principles involved has soothed untold suffering and saved millions of lives. The necessity and value of prompt and efficient first-aid in injuries needs no comment. During the war with Spain, in the Philippines campaigns, and in the war in South Africa it has been established that, by the prompt application of first-aid dressings, the loss of life and limb has been reduced to the lowest ratio in the history of warfare. The modern practice of surgery requires that the dressings applied to a wound shall not only look clean, but shall be surgically clean (that is, aseptic); free from germs. From the surgeon's standpoint, a piece of spotted linen may be a filthy rag; he does not judge from the looks, but by his knowledge of the effects.

In order that the beneficial effects of modern surgical methods may be applied to any wound, from accidents at home, in the shop, the factory, railway service, mine, camp, or wherever accidents may occur, Johnson & Johnson have devised a system of first-aid appliances. This firm is known all over the world as makers of surgical dressings that fulfill the requirements of modern surgery. They are the pioneers in making these dressings. They have revolutionized the methods of manufacture, and by their skill and industry have made the application of surgical cleanliness in modern surgery possible, not only in large hospital centres, but in the most out-of-the-way places. The prompt use of the material applied according to this system has saved many lives. This system has received the special endorsement of thousands of railroad, mining, and factory surgeons, as well as those connected with fire, police, and municipal departments.

The cabinet is so arranged and the contents so selected that temporary aid can be rendered by any layman, and when the surgeon arrives he will find proper material for the first dressing of any conceivable injury. The dressings are simple and complete, and the contents of the cabinet are not only applicable to injuries of any nature, but are sufficient in quantity to provide for a large number at one time. It is not essential to the successful use of this cabinet that the operator should be skilled in anatomy, physiology, or surgery. Any intelligent foreman by the aid of the accompanying Manual can render effective first-aid in all emergencies. In applying the wrong material. In other words, no harm can result from applying any bandage or material contained in the cabinet. The general directions accompanying these cabs are: "Send for a surgeon, and while waiting apply the proper bandage." The appliances in the Johnson's First-Aid Cabinet are similar to those supplied to the army and navy. The contents of the cabinet are two Johnson's First-Aid for wounds; two ounces Red Cross absorbent lint; one capsule iodiform gauze; six packages Red Cross absorbent gauze, each containing one yard; four packages Red Cross absorbent cotton, each containing 4 oz.; one spool Johnson's Z O' adhesive plaster, 1 in. wide: nine Red Cross cotton roller bandages, 2 in. wide; nine Red Cross cotton roller bandages, 3½ in. wide; nine Red Cross linton gauze bandages, 2 in. wide; nine Red Cross linton gauze bandages, 3½ in. wide; one jar carbonised petrolatum; two packages safety pins; one Johnson's First-Aid Manual.

The dimensions of the cabinet are: length, 21 in.; width, 14½ in.; depth, 3½ in. It is made of japanned metal, with strong hinges and fasteners, hangers to hang the cabinet on the wall, and convenient handles for carrying. The contents are so packed as to be readily accessible. Simple directions for the use of the various articles are printed upon the inside of the cover; and in each case a Manual is enclosed giving explicit directions for the treatment of injuries before the arrival of the surgeon.

Commercial Paragraphs.

WALTER S. KING, formerly with the Oregon S. & R. Co., at Sumpter, Oregon, has opened offices as a consulting metallurgist at Seattle, Washington.

The BYRON JACKSON IRON WORKS, San Francisco, has recently shipped a two-stage vertical pump to the Springfield Tunnel & Development Co., Sonora, Tuolumne county, California.

The ALLIS CHALMERS Co. announces that E. W. Lindquist, formerly chief engineer of the mining department at Milwaukee, is now permanently at the San Francisco branch house.

The C. O. BARTLETT & SNOW Co., Cleveland, announces that it has recently received the contract for a complete steel tipples from the Crow's Nest Pass Coal Co., Fernie, British Columbia.

PAUL STOCKTON is opening up a large marble quarry in Mariposa county, and will be in the market for the purchase of equipment for quarrying and stone dressing. His address is San Jose, California.

The DIXON CONCENTRATOR Co., Fort Wayne, Ind., has sold 16 of its No. 1 tables to the Champion Copper Co., Freda, Michigan, and three No. 3 tables to the Arizona Gold M. & M. Co., Patagonia, Arizona.

F. G. CLAPP has resigned from the U. S. Geological Survey and has formed a partnership with A. W. Bev, Jr., civil engineer, for the purpose of engaging in the practice of geological engineering. The office of the firm is at Pittsburg.

The WAGNER ELECTRIC MFG Co. are now well established in their new plant at St. Louis, Mo. The equipment is of the very best, and every means is taken to secure efficiency and economy in shop practice. The San Francisco branch has just moved to 312 Balboa Bdg., and a complete stock of the products of this Company is carried in San Francisco.
EDITORIAL.

PROPHESY of certain conditions in the business world for the coming winter may be made with a fair degree of confidence. The general feature of the situation at present is a shortening of stocks. The most necessary supplies are not being renewed, and a period of active demand must soon begin. The failure of dealers in coal to lay in the normal winter stock has been noticeable in all parts of the country. The same is true of dealers in lumber and all staple commodities. The result will presently be a traffic congestion, and a sudden increase in prices, both wholesale and retail, out of proportion to any actual recuperation of industry. Another noticeable feature of the summer months has been the widespread reluctance of the farmers to forward crops to market, despite the attraction of higher prices. This situation points to speculation and unhealthy conditions of the market in the late fall and early winter months. This would argue against any permanent advance in metal prices in the near future, with the prospect of spurious prices which may produce brief sensations. The copper market, which has come to be recognized more than ever as a sensitive trade barometer, has been weak and unsatisfactory throughout the month of August. There was a feeble but temporary advance, then a retreat to 13.12 cents on August 3. The price has since recovered slightly, standing now at 13.50. The foreign purchases have not been large, and it is currently reported that copper stocks abroad are ample for actual needs for a considerable period. Following their usual custom, the European brokers have replenished at the low prices prevailing, but purchases slacken with the least strengthening of the market. The indications are that the production of copper at present is largely in excess of any visible demands. Hence a marked rise in value must bring out large quantities of the metal, with the inevitable reaction in quotations.

CONSERVATION OF RESOURCES is the new slogan, and a right good one it is. Amid all the shouting and furor of the Roosevelt administration, amid the confusion of applause and vituperation, one great sobering conviction has been planted in the minds of the people. Mr. Roosevelt has convicted the nation of ruthless waste; he has bidden it pause and consider the future; he has shown the inevitable penalty of reckless dissipation of the gifts of nature. Perhaps this is the great contribution of this strenuous President to his people, by which his name will be held in esteem admitting of no qualification. The man who builds for the good of all men and of generations yet unborn, builds particularly well. He is in the largest sense a benefactor, and is advancing the development of the race to-
ward that regard for the rights of each individual in our common patrimony which has long seemed like an unattainable utopian ideal. Mr. George Otis Smith reminds us, in a recent address, of which we publish an abstract in this issue, of the strong words of a noted scientist, who said, "future historians will date the end of barbarism from the time when generations begin to feel that they rightfully have no more than a life-estate in this sphere, with no right to squander the inheritance of their kind." This is the new gospel of the practical world, which re-states the golden rule, and insists, with the old militant spirit of every prophet who has had a true message for the world, that it must be observed.

WASTE OF HUMAN LIFE has become one of the subjects to which our Government has lately directed special attention. In the coal mines alone fatalities to the number of 3124 are reported for 1907, which represent an increase of fifty per cent over those for 1906. This, of course, is phenomenal, but it justifies the investigation undertaken by the technologic branch of the United States Geological Survey to ascertain more accurately the conditions under which explosions occur. From these will naturally follow improvements in modern practice. To this end an explosion experiment-station is being equipped at Pittsburg. An agent has also been sent abroad to collect information concerning European methods, involving both measures for safety and for prevention of waste. The two go hand in hand, for the perils of coal mining are greatly aggravated by conditions leading to the production of dust, and to excessive quantities of fine coal which finds its way into the 'gob.' In the regulation of mining operations this country has lagged far in the rear of England, Belgium, France, and Germany. Restrictive legislation in those countries has become elaborate, and has been based upon the results of careful investigation by commissions representing applied science in its highest sense. In order that the United States may profit by foreign criticism without delay, invitations have been extended to those countries where efficient growth of mine-regulation has occurred, asking that representative experts in mine supervision be sent to inspect the coal mines in the several States and advise ways for their betterment.

ECONOMY in any particular always involves a correlation of economies in general. Neither evils nor blessings appear to come singly. So the conservation of natural resources reveals a chain of advantages. We pointed this out some time ago in showing how the preservation of the forests, to take these as a starting point, called for an extension of the use of creosoted timber, and how that necessitated a large production of creosote oil which can come only from bituminous coal-tar. That in turn demands an extension of retort-coking, replacing the criminal waste now ensuing from the almost universal American practice of making bee-hive coke. The bee-hive oven is almost obsolete abroad, while the skies over the Connellsville basin in Pennsylvania are red with the glow from spendthrift fires that should never be permitted to burn. This prodigal waste appears in every coalfield of the country. The adoption of by-product coking will yield a surplus gas which, if not otherwise needed, may be converted into electrical energy; it will produce many valuable distillates; and large quantities of tar which is useful as a binding material for road-metal, as has been demonstrated conclusively in the East and abroad. Furthermore, fixation of nitrogen takes place in the process on a large scale, producing ammonia which will be useful in absorbing the excess of sulphuric acid which must result from the suppression of fume from smelting-works. Thus the farmer will enrich his soil with inexpensive ammonium sulphate, and the smelter will at least become doubly his friend. The relatively close geographical association of great coalfields in America with centres for smelting, and with extensive sources of timber, is most important, and the development of such a chain of conservactive operations as we have outlined must shortly mark a forward step in our industrial life.

Creosoting of Timber.

WITH wealth being wasted in the bee-hive coking of American coals, and with creosoting of timbers appealing to the people as a practical and important means for checking the enormous draft upon the forests brought about by increase of population and expansion of industry, all the creosote oil used as a preservative in this country is still imported from England. The sole reason for this is that the American creosote is liable to contain impurities derived from other fuels than bituminous coal in gas manufacture, the domestic product being derived almost wholly from gas-liquors. This condition will be altered with the extension of by-product coking. Well-creosoted timbers last indefinitely. It is only an admission of imperfect work, or of the use of impure material, to attempt to set a limit to the endurance of wood which has been properly treated. Piles submerged 45 years have remained unchanged, and have shown the presence of eight pounds of oil per cubic foot of the timber, which is as much as could have been driven into the wood 45 years ago. Today the average quantity absorbed is about nine pounds per cubic foot, and rarely rises above fourteen pounds. These weights correspond closely to the weight of water removed from the timber in the process. The simple methods of coating timber with preservatives may do positive harm unless kiln-dried or thoroughly seasoned timber be employed. The coating will otherwise lock up moisture in the wood which will produce dry-rot, and soon leave only an empty shell. The same trouble used to occur with creosoted timbers before it had become customary to eliminate the original moisture. At the present time this is done by subjecting the timbers in the treating-cylinder to dry-heat from steam coils, and to live-steam, simultaneously, the temperature being kept below 200 degrees Fahrenheit for several hours. The creosote oil is then turned in, and the steam heating is continued by means of the coils, keeping the tem-
perature of the bath close to 220 degrees. Creosote oil is a distillate with a specific gravity of 1.04, obtained at a temperature exceeding 600 degrees. Consequently it will not evaporate at the temperature of the bath, but the moisture in the timber will continue to be given off. This is continued with the aid of about ten pounds vacuum per square inch, until the rate of elimination of water is reduced to one-fourth of a pound per hour. By that time the total water evaporated will range from eight to fourteen pounds per cubic foot of timber, and approximately the same amount of creosote oil will be re-absorbed in its place. To saturate the wood, however, force must be applied. The cylinder is accordingly flooded full of the creosote oil, and a pressure of twelve pounds per square inch is developed with a pump. The cost of creosoting on the Pacific Coast, where the oil costs about 16 cents per pound delivered, is from $20 to $25 per thousand feet board measure. The timber after treatment weighs more than the ordinary seasoned lumber, and the freight will be proportionally higher, this extra weight being about 300 pounds per thousand feet. In spite of all this, the use of creosoted timbers will undoubtedly soon become general for somewhat more than half the consumption underground by mining companies. Estimates made by the Government less than a year ago indicate that 45 per cent of all mine timbers fail because of decay, and 10 per cent are destroyed by insects. Against these creosoted oil will insure protection. Of the remaining 45 per cent, the waste amounted to 10 per cent of the total consumption, which would be distributed between treated and untreated timber where both were employed. There would also be a small additional expense from the necessity of applying a coating of creosote oil to the freshly-sawn ends of all timbers when cut for placing in position, since the preservative fails to penetrate entirely to the centre even under the most highly perfected methods of creosoting in vogue at the present time. Some failures to secure good results with treated timbers have come about through inattention to this detail.

Erosion and Sub-Soil Decomposition.

Erosion of rocks when covered with the soil of a tropical jungle puzzles a correspondent whose letter appears in another column of this issue. The question is quite as pertinent with regard to erosion facilitated by sub-soil decomposition of rocks in the North as in the South. There is no difference between the tropical mantle and the sub-arctic mossy 'muck,' say that there is more of it, and its decomposition-products yield active mineral solvents in greater abundance. In fact, the problem can not be localized. It is all one, wherever we meet it, and the influences operating are essentially the same. The organic acids leached from the soil, energetically attack the underlying rocks. The roots of trees penetrate to great depths, and not only force their way by expansion in crevices of the rocks, but secrete acids which attack the rock-constituents and open the way for further growth and penetration of the rootlets. Bacteria also flourish in the upper zone of decomposition of all rocks and hasten the processes of decay. The Pie Porri of the Bernese Alps, the famous 'Rotten Peak,' is undergoing bacterial decomposition at a rapid rate.

Erosion is commonly considered by the layman to represent chiefly the mechanical effects of heat and cold, of wind, rain, and frost. These are, to be sure, the true eroding agencies, but their larger function is to complete the work prepared in advance by chemical action. The siltates yield readily to the influence of waters carrying carbonic acid and the products of vegetable decay. Those silicates carrying iron in the protoxide form are the first to succumb, and in regions of moderate rainfall a red dis-coloration of the soil from the resultant ferric oxide is the certain indication of the chemical operations in progress below. In the tropics, and in any region where organic matter is abundant in the soil, this iron will be removed as soluble carbonate. The decomposition of the rock-forming minerals produces effects known as kaolinitization, epidotization, and the like, which represent in the aggregate a shrinkage of volume. Such is the net result, although rock-alteration does to some extent produce an increase of volume. The shrinkage from such sub-soil decomposition of rocks amounts to an average of about 60 per cent of the original volume. The actual erosion then is merely a question of the amount of rainfall, and of the carrying-power of the surface-drainage with respect to the soil particles, thus lowering the actual level of the country through removal of rock-material, both chemically and mechanically. In many places very beautiful examples of these progressive denuding effects are to be seen, where the loose pulverulent soil is succeded downward by increasing coarseness, passing gradually through every phase of rock-decomposition into the hard unaltered rock below. Hence it is seen that the soil offers no impediment to denudation, and if gold be present it will be concentrated in the streams as it is washed down from the valley-slopes, even though the rocks in which it occurred may never appear upon the surface.
**Personal.**

W. A. Irwin is at London.

T. Lane Carter is in Switzerland.

Frank H. Pressey is at Globe, Arizona.

R. P. Munroe is at San Diego, California.

John B. Farish has returned to Denver.

Arthur W. Stevens is now at Los Angeles.

John Morgan, of Denver, is at Fairbanks, Alaska.

William E. Harrison has gone to Pioche, Nevada.

William Nicholls, Jr., is at Berkeley, California.

H. E. West will shortly be in New Brunswick, Canada.

W. B. Kehoe has gone from Mexico to Fairbanks, Alaska.

Evan Fischer has returned to New York from a trip to England.

E. L. Ballo has moved from Pony, Montana, to Igo, Shasta county, California.

John Power Hutchins, of New York, is in Colorado examining dredging ground.

T. H. Jerks is now with the Canana, Rio Yaque & Pacific railroad, at Cucalco, Mexico.

R. C. Shaw left San José, Costa Rica, September 1 for California, by way of New York.

T. L. Oodh, who has been at New York for some time, has returned to Tonopah, Nevada.

H. L. Twright, of London, is in Bolivia reporting on the Ocati tin mines for English clients.

Robert M. Raymond, of the El Oro Mining & Railway Co., Ltd., El Oro, Mexico, is at Catalina island.

Alexander Legatt, of Butte, is at Miles City, Montana, making surveys of mining property for clients.

Alex Colledge, of Singapore, was in San Francisco, and will sail on the Laustatia for London on September 16.

J. H. Atkins, of Tonopah, Nevada, left San Francisco August 31 on a professional trip to the gold placers of Argentine, South America.

E. S. Petris is at Prescott, Arizona, and has recently completed the installation of a reduction plant for the Monica mines, near Kirkland.

Franklin R. Carpenter has recently completed a survey of the Uinta oilfields, of Wyoming, and is now in the Seven Trougas district of Nevada.

Norval J. Welsh has returned to San Antonio, Texas, after a six weeks' professional trip in the western part of Chihuahua, Mexico, and will shortly be at the Engineers Club, New York City, for an indefinite stay.

**Publications Received.**

The Lime and Cement Resources of Missouri.' By H. A. Buchler, Vol. VI, 2nd Series of the Missouri Bureau of Geology and Mines.

The Mineral Resources of the Philippine Islands.' Issued by Warren D. Smith, Chief of the Division of Mines, of the Department of the Interior, of Washington.

**Dividends.**

On September 4 the Bunker Hill & Sullivan Mining & Concentrating Co. paid dividend No. 122 of $75,000. This makes the amount of dividends paid since January 1 $530,000, and the total to date $10,446,500.

The Cenent Securities Co., of Denver, announces that F. L. Smith & Co., of New York, have been made consulting engineers of the Company.

**MINING AND SCIENTIFIC PRESS**

September 5, 1908.
General Mining News.

ARIZONA.
COCHISE COUNTY.

Work has been started on the group of lead claims, north of Dragoon, which Ben A. Williams recently sold to a company of El Paso business men. An incline shaft is being sunk on the vein.

GILA COUNTY.
(Special Correspondence.)—The big deposit of copper ore being worked by the Miami Copper Co., of Globe, was increased this week by the finding of the same character of schist strongly impregnated with copper on the Miami mine 2500 ft. northeast of the Red Springs shaft. The strike was made at a depth of 570 ft., and while the schist at that depth does not carry more than 1½% copper, the formation is the same as in the Red Springs shaft. The discovery also indicates the continuity of the vein for a length of more than 2500 ft., along the contact with Schulte granite, which means an increase of the ore tonnage that will make of it the largest copper deposit in the Globe district. Developments at the Montgomery mine are steady, as usual, and No. 4 winze is down to a depth of 151 ft., with the station at the second level nearing completion for cross-cutting. The drifts east and west from the cross-cut at the first level continue in a superior quality of good shipping ore, the east drift being 55 ft. and the west drift 179 ft. Dally shipments of ore are being made from the upper levels which average 50 tons. The working force remains the same, but E. M. White, who is superintendent, believes that it will be necessary to increase the number in a few weeks. A new pipe-line has just been completed from the Winnie well to the new hoist situated at the entrance of the north cross-cut adit. This was done to insure a permanent supply of water for the new steam-plant in course of erection. The foundations for the new engine and compressor are nearly completed and it is hoped to have the new steam-plant in operation early in September. The tramway from the north cross-cut orehills is being put in readiness for work and this will lessen expenses in the handling of the ore. Besides the extensive operations in the mines, the Warrior Co. is also giving attention to surface improvements in the way of buildings, which include a private office for the superintendent, a foreman's office, assay and engineering offices, and an addition to the already large boarding-house. A light and harmless cave-in on the Orphan Copper Co.'s property a few days ago disclosed quite a fine body of rich ore. The work of equipping the shaft for better work has been in progress for some weeks, and the head frame has been completed and the hoist will be put in at once.

Phoenix, August 29.

YAVAPAI COUNTY.

The United Gold Mines Co. has developed its Ohio claim to a depth of 390 ft. and uncovered some good ore. The new mill is now ready to start on a steady run. Preparations are being made to install a cyanide plant in connection with the mill. The plant includes four Nissen stamps and three Willey concentrating tables. The mill is at the Arizona mine, near Congress, which is developed to the 400-ft. level. There is a large tonnage of ore blocked out for stoping as soon as the mill is put in operation.

CALIFORNIA.
AMADOR COUNTY.

James Mushett and E. W. Kelly have started working a piece of placer ground on the middle fork of Jackson creek on the Kelly ranch, a mile northeast of Jackson. It is claimed that that piece of land has never before been worked.

CALaveras COUNTY.

I. M. Kuhn has taken a two-years' lease on the upper levels of the Esperanza or Boston mine, near San Andreas. His purpose is to start 10 stamps of the 30 now on the property, and will add a cyanide plant by which he expects to mine, mill, and cyanide the ore for $1.50 per ton. The ore will average 1% per ton, and it is estimated there are 1,000,000 tons above the adit-level available for milling. The company is expected to take over the property in a few weeks, and will erect a larger hoist and sink the three-compartment shaft 1600 ft. deeper and ultimately add 10 stamps. The Peak Ranch and the Deep Gulch properties, consisting of 249 acres of patented land and three locations adjoining on the west, have been bonded to George Cahalan of Santa Rosa, who is organizing a company to commence work on the two properties. The property of the Del Monte Mining Co., situated in the Sheepbranch mining district has been sold to the Del Monte Goldfield Mining Co., with offices at Goldfield, Nevada.

NEVADA COUNTY.
(Special Correspondence.)—The Noramlagua mine has been bonded by an Eastern company represented here by Samuel Colt. The terms of the bond are withheld from the public, but it is known that a good cash payment was made. The Noramlagua is just below the Deadman Flat district and is credited with an approximate production of $1,000,000. The pump and hoist have been put into commission at the Midas and two shafts are sending the shaft down rapidly. The new shaft will cut the vein at considerable depth below the old workings. The shaft at the Idaho-Maryland has been unwatered to the 900-ft. level and the work of re-timbering it is going forward rapidly. The 700-ft. level has been cleaned up for 400 ft. On the west drift on the 500-ft. level a good shot or rich ore is being developed. The surface plant is being put in first-class shape. A good body of ore has been developed in the Birchville mine, near Graniteville, and arrangements are being made for the immediate erection of a 10-stamp mill. It is reported that operations will be shortly resumed at the Grizzly Flat mine. Eastern people are understood to be interested. A 5-ft. vein of rich ore has been struck on the 300-ft. level of the Birchville mine. The bond on the property has been extended. Local people have located the Sierra Queen group of quartz claims at Camptonville and expect to work their holdings on a large scale. The veins range from 6 to 8 ft. wide. Considerable surface and underground work is going on at the Snowden Hill group. The bed-rock tunnel is being driven steadily to intersect the gravel channel. Several
men are employed in the work. L. C. Heiler is general manager.—A 12-ft. vein of ribbon quartz running from $6 to $7 per ton has been struck in the face of the drift at Ancho mine. The 10-stamp mill is running steadily. Austin Hunt is superintendent.—The Champion Co. is defraying its operating expenses with the revenue from tributes. About 35 men are working.

Grass Valley, August 31.

INYO COUNTY.

An Exposition of Mineral Resources of Inyo will be held at Bishop, October 13 to 16 inclusive. The committee, of which W. Gillette Scott is chairman, announces that it will be glad to receive specimens of ore representative of Inyo county and adjacent territory. Opportunity will also be given for the exhibition of machinery and other devices relating to mining.

SAN BERNARDINO COUNTY.

J. H. Reynolds, of San Diego, has been examining the Long shot claim, at Hart, for a new San Diego company, recently promoted by A. L. Gottsebaren. It is reported that Mr. Reynolds will advise his clients to not only proceed with the development of that property, but also pursue the Bishop & Martin lease on block 3 of the Oro Belle No. 2. It is probable that both properties will be started at one time. The Oro Belle and the Oro Belle Fraction claims have recently been surveyed for patent. The Oro Belle Mines Co., the owner of these claims, is being financed in Duluth, Minnesota. W. B. Andrews, who has charge of the sale of stock, reports that he expects to have sufficient funds to start work some time in October. The company plans to spend about $50,000 in sinking a 300-ft. shaft and doing lateral work.

SIKIYU COUNTY.

(Special Correspondence.)—The United States & British Columbia Mining Co. has finally closed a deal with H. B. Wintering and F. H. Ogood for the Big Cliff group of claims on Russian creek, after allowing one option to go by default. The new owners have put a large crew of men to work and active development will be pushed.—A $10,000 pocket was discovered last Wednesday by Dan McCarthy, one of the best known and most successful pocket hunters in this county. The "find" was made just half a mile from the old mining town of Scott Bar, the point where gold was first discovered in Siskiyou county away back in 1851. One piece of the honey-comb gold found in the pocket weighed five pounds. It was found at Scott Bar that the late James Lindsay found a $3500 nugget shortly after the first discovery of gold in the district.—The Klondyke mine on Ash Creek has finished the installation of a 75-ton Huntington mill and are waiting for the Siskiyou Electric Power & Light Co. to extend its line down the Klamath to begin milling.

Yreka, August 29.

TOULUMNE COUNTY.

Contracts for construction of two adits, each 100 ft., in the Tunny have been awarded to J. A. Keyes. —The Garfield, lately named the Georgia, near Carter's, sold by Sheriff Sweeney to satisfy a judgment in favor of E. M. Carr and against the Floyd Mining Co., has been redeemed by J. L. Gibbs.—Peter Nave and William Musso have bonded their quartz mine at Italian Bar to a syndicate of Santa Barbara capitalists, the consideration being $29,600.—The Sounsel shaft has been equipped with transformers and will be run by electric power in the future. The Sounsel is owned by the Bagdad-Chase Co., which has a lease on the Ralph mine. At the latter property a hoist has been installed and eight men are sinking the shaft.

COLORADO.

CLEAR CREEK COUNTY.

(Special Correspondence.)—A rich strike was made this week in the property of the Lincoln Mtn. M. & M. Co., operating on Lincoln Mtn. At a distance of 1200 ft. from the entrance of the adit a blind vein was intersected, a body of ore being uncovered that is from 4 to 6 in. wide.

Assays run from $500 to $700 per ton in gold. The discovery came entirely as a surprise and considerable interest is being manifested among owners of mining properties in that locality. The adit was started for the purpose of cutting the 500-ft. level of the Virginia City shaft, the objective being yet 200 ft. distant. —The Capital M. & T. Co. started work this week in the construction of a sampling and assay building. It has been decided that hereafter all ores from both the mine and mill shall be thoroughly sampled before being sent to the smelter. By working along these lines there will be little trouble in separating the mill ore from the smelting material. The average grade of the concentrate now being sold is 10 oz. gold and 6 oz. silver per ton. The smelting ore brings returns running from $275 to $305 per ton in gold. R. C. Patterson has been appointed to the position of mill manager.—A number of Pittsburg, Pa., capitalists won't camp this week and it is stated that work will soon begin upon the Hall adit. The bore will be driven ahead, while driving is to be put under way upon a number of veins already intersected. B. J. O'Connell, of Georgetown, is manager.—Work was resumed this week upon the Merrimac group of claims, situated on Kelsey Mtn., West Argentine. The adit, now in 152 ft., is to be driven steadily forward for the purpose of intersecting the Mtn. orebody. From surveys the Merrimac vein will be reached in 50 ft. High-grade ore was mined in the shaft workings, but as work could not be carried on during the winter months, it was decided to drive an adit. J. T. Johnson, of Denver, the owner, purposes driving the adit for 600 additional feet.

The Ruby Argentine M. Co., operating in the Peru district, is continuing its prospecting work in the vicinity of the mine. The company plans to spend about $50,000 in sinking a 300-ft. shaft and doing lateral work.

LAKE COUNTY.

It is believed that the Iron Silver Mining Co. will erect a $12,000 ore-house at the Tuscon and also resume operations at both the Moyer and North Moyer properties. Fremen Woodruff and H. G. Stevens, of Detroit, were in Leadville last week and it is believed that their visit was for the purpose of completing the details. A. S. Sharp is making extensive preparations for activity on the Ruby property in Weston pass, upon which he recently took a lease. Mr. Sharp will continue as superintendent of the Aurora in
town gulch.—The Central Colorado Power Co. expects to have the transmission line complete between Shoshone and Leadville before the first of the year. This will enable mining properties in all parts of the district to equip with electricity at a reasonable rate. One is waiting for such an opportunity.—A force of men is at work dismantling the old Forest Queen property on Breeche hill. This old mine is now being worked through Yak tunnel, and the surface plant is no longer necessary. The Forest Queen continues to produce some good lead ore. The operations through the Yak have been successful in every way, and later, it is figured, this property may be more extensively worked.

Excavations have been started for the pyritic smelter on the Strattons, near Ironon. In a comparatively short time the plant of machinery will be on the site and the work on construction begun at once.—W. S. McCarthy and E. C. Bacon have secured a lease on the Poland claim on the western slope of the Engineer mountain range, up the Uncompahgre, and the work of cleaning it out has begun. It is the expectation of the lessees that they will be able to ship good ore from the property immediately. Several cars of high-grade silver-ore were shipped out of the Poland years ago and some of the vein is still exposed.—Within a few days following the installation of the new machine drills, the Koehler tunnel, one of the largest enterprises on Red Mt., has been closed down and the men discharged. While the cause of the abandonment of the project is a matter of dispute, it is asserted that in a short time the work will be resumed.—George Crawford arrived in Ouray and Red Mountain last week and has paid off a part of the indebtedness of the Red Mountain Railway Mining & Smelting Co. and it is believed the properties of that company will be started soon.

SAN JUAN COUNTY.

The Wyoming, on Engineer Mt., is working a force of 12 men, who are engaged in sinking a shaft on a vein of high-grade ore, samples of which assay 1 oz. gold and 1900 oz. silver per ton. The Wyoming is owned by the Pittsburg Mines & Metal Co. and has ample capital for the development.

TELLER COUNTY.

The foundations for the 10-stamp experimental mill which the Portland is building, at Cripple Creek, are practically completed. The plant is being built to sample the ores of the mines and also about a million tons of dump, which it is expected will run $2 to $4 per ton. The experimental plant will be under the direction of G. M. Taylor, who is superintendent of the Company's mill at Colorado City.—Bender and associates have been forced to quit work on their lease on one of the blocks of the Strattons Independence, on Battle Mt., on account of a big cave-in which occurred recently. About 1000 tons of waste has covered a considerable amount of smelting-grade ore already sorted in one of the stops. The mineral was being broken from a junction of four veins. The lease sides the Portland property.—A new shaft is being sunk from surface on the Ivanhoe claim, of the Greater Gold Belt Mining Co., on Gold hill near Badger station on the High Line Electric road. The new shaft is situated at the base of the dump of the former main shaft, these workings having caved.

IDAHO.

BLAINE COUNTY.

(Special Correspondence.)—The Crossus, belonging to the Crossus Gold & Copper M. Co., is in a granite formation, and is situated four miles west of Hailey. Most of the other mines of the Wood River district are in limestone. On the Crossus group the granite is considered a cap-rock, overlying the limestone. The Crossus has been worked with a varying degree of success for a number of years and has been regarded as strictly a gold mine: but within the last year or two a lead vein was discovered at 600 ft. depth. The gold vein, which has been opened by an 800-ft. vertical shaft, strikes east-west through granite and stands in almost a vertical position, though there are some varia-

tions in dip on different levels. This vein ranges in width from 20 to 60 ft., the vein filling consisting of quartz, granite, and porphyry, carrying gold and silver associated with iron and copper sulphide. The richest ore is found in shoots next the walls, there being low-grade ore and nearly barren streaks in the central part of the vein. The lead vein is also nearly vertical and has a strike that diverges but little from an east-west course. The two veins join near where the shaft was sunk and appear to run side by side, between the same walls, from this point westerly. The extensive work on the lead vein at the 900, 700, and 600 ft. levels shows it to be a strong vein, carrying high-grade silver ore, accompanied by $7 to $14 per ton. A concentrating mill is being erected that will have the capacity of 150 tons of ore per day. Its equipment consists of crusher rolls, jigs, Hunting- son mills, amalgamating plates and tables. The plan is to mill the ores from the two veins separately. The plant is expected to be in operation within 60 days, electric power to be used. The equipment is nearly all on the ground ready for installation. A new air-compressor is to be installed at the mine, capable of operating 12 to 15 drills. It will be belt-driven, electrically operated. The hoist is operated by steam power. It is intended, however, to do the hoisting by electric power some time later. Sam E. Rife, one of the principal stockholders in the Crossus company, is general manager. R. J. Soble is being the mine superintendent.

Hailey, August 26.

IDAHO COUNTY.

The Golden Crown mining property, owned by George S. Young, of Elk City, will start at once sinking a shaft. Ore showing free gold has recently been struck in an adit in only 60 ft. It is said that a 20-stamp mill will probably be built on the Penn-Dixie. S. R. Gayton, of Bradford, Pa., has recently made an examination of the property.—The Graham Ross Co., which has a bond on the Anaconda mine in the Newsome district, has been organized and will be known as the Nevada Green Hill Consolidated Co. The new company will resume work at the Anaconda mine within two weeks. An adit on the property is already in 1070 ft., and a cross-cut, started at 1500 ft. from the portal, is 70 ft. long. The Gold Point Mining Co. has ordered a 40-ton Chilean mill for its property on Red river. The plant is due at Stites September 29. O. L. Smith is manager.

SHOSHONE COUNTY.

(Special Correspondence.)—Many features of interest have marked the progress of the mining industry in the Coeur d'Alene throughout the past week, of which perhaps the most encouraging were the increased dividend disbursed by the Hecla mine, at Burke, and the announcement that the Stewart mine, at Wardner, is to resume work. Throughout the recent depression of the metal markets the Hecla mine has been paying dividends at the rate of one cent per month, except for a month or two, in which the property has been closed down. The dividend for August, however, has been declared at the rate of two cents per share, and involves the disbursement of $20,000, making a total disbursement for this year of $90,000, and a grand total of $1,610,000.—E. J. Carter, one of the wealthiest stockholders of the Stewart Mining Co., has made the announcement that the affairs of the Company, which have been considerably tangled in a legal direction, are about to be straightened out, and operation of the mine and mill resumed. This will be one of the most important events of the Coeur d'Alene this year. The mill is practically new, with a capacity of about 150 tons per day. Big bodies of ore have been opened in the mine, and just after the completion of the mill several shipments were made to the Davis Smelting & Refining Co. Cushing Moore, of Wallace, has been selected by the Republican party as the candidate who will make the race on the State ticket for the office of State Mining Inspector.—The 1900-ft. adit of the Springfield Mining Co. has struck the vein at a depth
of 500 ft. under the upper adit and about 700 ft. from the surface. The lead at this point is about 22 ft. wide, and on one side of the adit carries six inches of good copper ore, and two feet of the same ore on the other side. No assays have yet been made.—Sinking is to be resumed on the property of the Anchor mine, at Burke, on which the recent sensational strike of ore carrying all the way from 2900 to 4900 oz. silver per ton was made. The mine was closed down temporarily, pending the installation of electric power for the compressor. It is intended to sink the present shaft to considerable depth and then to drive on the lead.—The stockholders of the Mineral Farm property, near Macon, have been asked to vote on an assessment to be levied by the company. This assessment will be either at the rate of three mills or of five mills per share, according to the vote of the majority. Accompanying the ballot sent to each shareholder of the company is a full report of the workings of the mine. The principal purpose for which this assessment will be levied will be the driving of an 1100-ft. adit and the sinking of a 250-ft. shaft. The company estimates that the cost of this work will be in the neighborhood of $30,000, which will also cover the cost of a full equipment of machinery sufficient for all present purposes.—A report which appears to be well founded is in circulation to the effect that the Lacrosse placer mining property, on Cedar creek, has been purchased by a syndicate of Kansas City capitalists. Among those who recently inspected the property are E. H. Keinzie, J. H. Neff, Harry Evans, and Harry Duke, all of Kansas City. Bids are being asked for mining and dredging machinery to be put on the ground without delay. It is claimed that the property is easily dredgeable and that every cubic yard of ground now being handled is yielding a return of 76c. to 81. No statement has been made as to the monetary consideration involved in this deal, but it is understood that a company of the gentlemen interested will be formed at Kansas City at once. The Lacrosse Bros. will continue to manage the property.—A contract for 300 ft. of adit work has been let to James Backlund, on the property of the West Hecla Mining Co. The adit has already been driven about 1000 ft., but it is calculated that it will have to be extended from 150 to 200 ft. farther to reach the main lead. Arrangements will be made in the near future for the installation of six drills. It is believed that the Company has the lead of the famous Hecla mine.—Excellent reports continue to come from the property of the Clearwater Mining Co., in the Clearwater district. A large amount of machinery has recently been put in at this property, and work is about to commence at once in the sinking of a double-compartment winze from the lowest adit. This property has been developed by means of three adits, in all of which a good showing of ore has been made. Assays of this ore run from 18 to 20% copper, and some gold. Up to the present time the property has been hauled by means of a small hoist, air being supplied by a pipe-line from No. 2 shaft. The permanent equipment has been ordered and will be on the ground in due time to facilitate the sinking.—Kear- sarge No. 4 shaft of the Oconee Con. Mining Co. has reached a depth of 250 ft., from which point a cross-cut is being driven to the lode. The method employed in sinking this shaft differs from the customary way, in that, instead of sinking the shaft directly in the lode and running the drifts into the shaft from opposite directions, the shaft is put down in the foot-wall, independent of and parallel to the lode. Cross-cuts are driven at suitable intervals (100 ft. or more) to the lode, and from these the drifts are run, as in the old method, parallel to the strike of the lode; the

Phoenix Mill of the Keweenaw Copper Co.

Quincy No. 2 Shaft House Which is Being Replaced by a Steel Structure.

Michigan.
Houghton County.

(Special Correspondence).—The Keweenaw has recently started operations at its Phoenix mill. The first ore to be crushed was a part of the 60,000-ton stock-pile which has accumulated at the mine. Although the mill is equipped with but a single head, with a capacity of about 300 tons per day, it will suffice until the completion of the new mill, which the company plans to erect at the mouth of the Montreal river, on Lake Superior. In addition to the head mentioned, the mill equipment comprises 16 jigs, 12 of which are of the Cleaves design, while the remaining four are of the Woodbury type. The rehabilitation of the mill, which has been in progress for the last six weeks, has resulted in the installation of entirely new and up-to-date machines. At the mine the improvement in the lode is very noticeable as depth is attained. The shaft is at present bottomed at the 13th level, a depth of 1125 ft., where the lode shows a width of 11 ft. Since the opening of the mill all attention has been centred upon stopping of the lat- terals. There is at present about two miles of openings in the Medora shaft, and on all sides are evidences of the unmistakable richness of the ground. The third level, which extends at present for a distance of 1900 ft. east and west, will be continued west for a distance of 1200 ft., at which point it is the intention to sink a second shaft. Pits have already been sunk through the overburden for a distance of about 15 ft., and sinking and blasting will be again taken up.—Work on the new steel shaft-house at No. 2 shaft of the Quincy is progressing rapidly, and already the framework is nearly completed. The huge wooden struc- ture which has served for years will be entirely dismantled and the crushers and other machinery transferred to the new house as rapidly as the latter is ready to receive it. The Quincy already has two steel shaft-houses at the extreme northern and southern portions of its property, which comprises a total of 1320 acres. The Mesnard shaft, on the north, has reached a depth of about 4500 ft., and has pushed its working laterals into the 800-acre tract purchased from the Arcadian two years ago. It is through this shaft, and a new one which is at present designated as No. 9, that the company expects to explore the Arcadian lands. The new shaft is situated about 2800 ft. west of the Mes- nard. An old shaft, sunk by the Clark people in the early days, will be enlarged to three compartments and deepened. The temporary equipment consists of a boiler and a small hoist, air being supplied by a pipe-line from No. 8 shaft. The permanent equipment has been ordered and will be on the ground in due time to facilitate the sinking.—Kear- sarge No. 4 shaft of the Oconee Con. Mining Co. has reached a depth of 250 ft., from which point a cross-cut is being driven to the lode. The method employed in sinking this shaft differs from the customary way, in that, instead of sinking the shaft directly in the lode and running the drifts into the shaft from opposite directions, the shaft is put down in the foot-wall, independent of and parallel to the lode. Cross-cuts are driven at suitable intervals (100 ft. or more) to the lode, and from these the drifts are run, as in the old method, parallel to the strike of the lode; the

Wallace, August 19.
NEVADA.

ESMERALDA COUNTY.

Between 3000 and 4000 tons of ore on the Biegole dump on the Consolidated has been purchased by the Nevada-Goldfield Reduction Co. The price paid is not made public. This dump rock will be used to 'dilute' the high-grade ore purchased by the Company and worked in its local stamp-mill. —Work has been resumed by the Midnight Pawnee Mining Co. on its property in the Diamondfield section of the district. A cross-cut is being run on the 400-ft. level to pick up the Black Butte lead. —Work was begun last week by the Little Goldfield Mining Co. on its long-term lease on the Goldfield Souvenir estate. The Company will also develop its fraction adjoining. —The Goldfield Apex Mining & Leasing Co., recently financed by Frank P. McNell in Salt Lake City, has started work on the lease which it holds on blocks 9 and 10 of the Goliocada. The property is equipped with machinery and has a shaft down 150 ft. The first stall will be cut at 300 ft. and the shaft will be continued down to 500 ft. —The Wonder King M. & L. Co. made its first shipment from its Rawhide property last week. It consisted of two lots of 15 tons each, one of which assayed $361 per ton, the other being the general run of the vein, which assays $76. —John Franks, backed by Philadelphia capitalists, has secured a bond and lease on the Buster mine of the Lida Queen Mining Co., in the Lida district, and will start up the mill early in September. He has opened up two shoots of ore in the south vein. He will put up a hoist and sink the inclined shaft deeper. —The mines of Goldfield produced during the week ending August 29 a total of 2388 tons estimated to be worth $175,520. During the same period the Tonopah mines produced 6675 tons of an estimated value of $178,425.

STEVE COUNTY.

Since sinking was resumed in the Misipah shaft, at Tono-

pah, the management has changed its plans somewhat. It was the intention at first to send the shaft down to the 1300-ft. point and start extensive prospecting work from that point, but it is now thought advisable to continue sinking until the shaft is down 1350 ft. and start the pros-

tecting work on that level. During last week the shaft was lowered 35 ft., the adit now being down 1140 ft., showing no change in the formation, which is rhyolite-
dacite. —The pipe-line from the Tonopah Extension power-

house, which is to furnish air for power to run addi-
tional machine-drills in the MacNamara mine, has been completed and four additional drills were set to work last week. This makes eight machine-drills in operation in this property, half of which are working in ore, the bal-

ence on development work. During the past week four carloads of ore, averaging 50 tons each, were sent to the smelter, and three carloads to the mills, making the total week's shipments 350 tons. —Milo Plemens, of Manhattan, will purchase a hoist for the lease which he holds on the Litigation Hill. —The first shipment of bullion from the new $2 stamp mill at the Homestake-King Con. prop-

erty was made last week. It consisted of three bars weighing a little more than a 77 lb. Troy, estimated to be worth about $17 per ounce.

WASHINGTON.

FERRY COUNTY.

(Special Correspondence). —A steam-boathast has been re-

ceived at Danville, for the Pacific Dryfus mine. —The first shipment of coke from the Hill Mill Mine Company, which has been received and is being installed. —The Silver Leaf has shipped a load of silver-lead ore from Cowada camp to Rickey Rapids, a steamboat landing on the Columbia river, to be transferred to the Great Northern railway at Myer-

Falls, in transit to the Everett smelter, on the Pacific coast. From bucket samples this ore is estimated to assay over $100 per ton. —A steamer has been put on the Columbia river, to run regularly to Rickey Rapids, which will give cheap transportation to the Cowada mines and stimulate development.

Republic, August 28.

STEVENS COUNTY.

(Special Correspondence). —At the First Thought mine two new piers have been added to the aerial tramway. During July, 31 cars of ore were shipped, exceeding the shipments for the month of April, during which ore was shipped than during any month in the history of the mine. —At the First Thought Extension camp living quar-

ters have been completed and the mine is now under active development. Great results are expected from this prop-
erty. —Foul air in the Orient, and also in the Copper Butte mine has compelled the miners to work on short shift, and the managers are planning for the best means of controlling the fumes. —The mining of the Wilson mine has accumulated development of the Globe mine that the Company has de-

cided on building ore-bins, which are now in course of con-

struction. —Additional funds have been secured for the Trojan mine, and a gasoline engine, blower, and additional pipe have been ordered. Work on the long adit will be re-

sumed as soon as the new equipment arrives. —At the Roy mine the adit is expected to be finished the adit is now in 315 ft. At a stockholders' meeting of the Trophy G. M. & M. Co., recently held at Orient, H. L. Schermerhorn and H. D. Trunkey, of Spokane, Wash., and James T. Dolan, C. E. Legg, and A. A. Anderson, of Orient, were elected directors. The executive officers are J. T. Dolan, president; C. E. Legg, treasurer; R. O. Mc-

Clutock, of Spokane, secretary. —Sedimental strikes of free-gold ore have been reported from the Bescher mine. The working force has been increased, and ore is being sorted. As soon as sacks arrive they will be filled and the first ore from the property, under the present management, will be shipped to the smelter. John Gilpin is superin-
tendent. The mine has been thoroughly sampled by R. M. McEntire, consulting engineer, and the company, confident of the mine's worth, on a dividend basis, has resolved on work-

drawing the sale of treasury stock. It is believed the re-
turns from the first carload will go a long way toward pay-

ing for development and additional equipment. —At the Second Thought mine the shaft, at a depth of 25 ft., has struck the vein, and the ore is found to be identical with the First Thought ore, and only 500 ft. distant from the latest strike in the First Thought mine. The First Thought mine runs 800 ft. through the adjoining Second Thought ground.

Orient, August 26.

CANADA.

BRITISH COLUMBIA.

Coke supply for the Boundary smelters is still an uncertain quantity, resulting from the recent crippling by fire of the shipping facilities at the Perusie ovens. —The smelter and mines of the Dominion Copper Co. have now been tied up for nearly three weeks for lack of fuel. The Company arranged for a supply of coke from the coast, but through delay of the Canadian Pacific railroad it has not arrived. —The Granby smelter is operating five furnaces during the past week, but coke has been consumed sparingly. Interviewed in Spokane, Jay P. Graves, general manager for the Company, denied any pos-
sibility of the plant shutting down. When assured of suf-

ficient coke the Company will operate at regular capacity again. —The Snowshoe property has not resumed as yet on account of the uncertainty of the coke situation, but instructions to begin operations are now being expected daily. —The only mining company in the Boundary not affected by the coke shortage from the Crow's Nest Pass is the B. C. Copper, whose ore shipments and smelter treat-
ment for the past week ranged around the high-

water mark. Coke for B. C. Copper comes from Coleman, Alberta, and the shipments were not interfered with by the recent Pass Ire.
Special Correspondence.

JOHANNESBURG, TRANSVAAL.

The industrial gloom prevailing throughout South Africa has been intensified by the closing down of the De Beers mine, in speedy succession to the Dutoitspan. The actual number of white employees retrenched in consequence of this further curtailment of the operations of the Consolidated is 200, but the fact that these men and their dependent families are in town where there is no scope for re-engagement, and that at least a year of comparative inactivity at the mines must prevail, has placed the town, so flourishing a year ago, in a position of critical distress. The situation is the more deplorable in view of the Rand's inability to absorb Kimberley immigrants in search of work, and there will be another batch of recruits to the army of unemployed. Many of these are certainly men of the character and capabilities, willing to turn their hands to anything.

As a mild, though wholly inadequate, set-off against the distressing closing down of the De Beers mine, we have experienced a small measure of hopeful excitement in the proclamation of new diamond-diggings in the district of Barkly West. It is estimated that as many as 1,000 tons per month, in the shape of new claims (60 by 30 ft.), were pegged by holders of a digger's license, permitting each to take up one claim. Some of the stones won in this district are of the finest quality, and it is most sincerely to be hoped that the peggers will be able at least to maintain themselves upon the field until more beneficial and less precarious avenues of employment can be found.

The recent retrospective Digest of the Journal of Mining and Metallurgy, issued by the Chamber of Mines, shows that, on a tonnage mined of 1,458,499 tons, Rand working costs averaged 18s., and the yield 35s. 6d., allowing an increased working profit of 3d. per ton. The most notable companies from the standpoint of low expenditure were, in June, the Robinson, with costs at 12s. 9d. per ton (slightly increased owing to temporary misfortunes), the Simmer & Jack, 13s. 1d., the New Consolidated De Beers, 13s. 6d., Goldenhans Estate, 12s. 10d., Gencairn, 13s. 11d., and the Knights Deep, 14s. The achievement of the last-named property, which had costs three years ago among the highest on the Rand, with 4s. for pumping alone, is especially remarkable. One of the Eckstein Central Administration mines, where the costs remain comparatively high (21s. 6d.), is the New Consolidated De Beers, in which the manager and the manager of the group, has appointed his former mine-captain of the Robinson (G. Hussey, of the United States) as manager, no doubt with a view to introducing the methods of underground administration which have raised the mining efficiency of the Robinson to so high a level. It must be noted, for those consequently tempted to compare the fortune-costs upon the two mines, that the New Modderfontein reefs are narrower, and that the new manager will probably not find himself in control of miners of the proficiency of those at work in the Central Rand.

A few years ago reports of bore-hole strikes or other notable developments in the Far East Rand were of monthly occurrence, but lately we have had our attention absorbed by two or three special points of interest. Diamond-drilling has ceased in the Rand, but 300,000 feet of satisfactory operations of mine development constitute the line of activity followed. The property of the Brakpan mines has on this account risen to a position of great significance, for, from its vertical shafts is being proved an extensive area of deep-level ground, which is far from any developed mines, and covers a portion of the Rand basin, wherein the reef lies nearly flat, and its possibilities but slightly determined. The No. 2 shaft of this mine, noted for the record-speed of sinking attained in it, reached its goal last week. At a vertical depth of 3695 ft. the reef (representing the series of the Central Rand) was reached and ore was found assaying 16 dwt. 4 gr. over a width of 81 6% in., a width quite phenomenal for this region. This valuation being obtained from sampling around a shaft 45 by 9 ft. in dimensions, is clearly of much greater importance than any of the bore-hole returns upon which it has been necessary to base estimates largely in the past. No. 2 shaft, in which the reef dips at an angle of 8°, is 400 ft. on the dip of No. 1, which cut the reef nearly a year ago, and from which development results have lately been satisfactory, though not up to the high standard of possible return indicated by the new strike. The assay-values revealed in No. 2 form a fitting reward for what has been one of the most creditable pieces of work in the mines, and the two shafts are much talked of. The reef's significance, as summarized as follows: The first sod was cut in May 1905; a hoisting engine was put into operation when 100 ft. had been sunk; the shaft was timbered with pitch-pine to 300 ft., and Tasmanian stringy-bark below; in April 1907, at a depth of about 1200 ft., a chamber was cut for a three-wheel Gould electric pump; in July 1907, record-footage of 264 ft. was made, from 1890 to 1894 ft., at an inclusive cost of £22 19s. 6d. per foot; the average rate of sinking from 1894 ft. to the reef (3695 ft.), was 161 ft. per month. The shaft, of seven compartments, was sunk by hand-labor working three 8-hr. shifts, and one-ton buckets were used throughout.

As anticipated, the Gold Law has received a large share of Parliamentary attention during the current session, and the Minister of Mines', Bill, discussed frequently in the public press, have been raised in due course by members of the Opposition. It has fortunately been recognized that the future of the country depends to a large degree upon the conditions under which its mineral exploitation is to be advanced, and that consequently such important questions as open-burrowing, road-making, and the like must not be settled hastily under the influence of party politics. A select committee has been appointed to deal with the bill, comprising the Minister of Mines, the Colonial Treasurer, F. Drummond Chaplin, Sir Willem van Hulsteyn, and Mr. Jacobz.

A certain farm, Zwartkop No. 52, situated a few miles to the north of Krugersdorp, has been recently sold by a very wealthy firm of objects collectors, and the great unsolved problems of Witwatersrand geology. Apart from the question of the origin of the Main Reef gold, which was re-suscitated by Professor Gregory last year after two decades of intermittent debate, the most crucial riddle calling for solution is whether the Witwatersrand formation is younger than the northernmost bos of granite, from which the strata lie at a distance of 200 miles from the site of the main reef, and the like must not be settled hastily under the influence of party politics. A select committee has been appointed to deal with the bill, comprising the Minister of Mines, the Colonial Treasurer, F. Drummond Chaplin, Sir Willem van Hulsteyn, and Mr. Jacobz.

so far met with success that the scope of investigation is likely to be extended beyond metallurgy. There is, indeed, no reason why similar attention should not be paid to novelties of pure mining and mechanical application, provided they promise to be of practical benefit to the subscribing members. The membership now comprises all the big groups of producing mines with the exception of the Goerty and Barnato administrations.

In the letter from Johannesburg, published on June 28, it was wrongly stated that no attempt was made to sort out waste rock at the Langaute Deep. As a matter of fact they did it, but the machinery was not ready. In 1894 the mine was given up by its former owners as a bad job, but Mr. Goldschmid and his Paris friends decided to make another effort. For some years want of harmony on the board, and other matters of similar character which need not be raised up now, prevented progress being made. Small dividends were distributed in both 1896 and 1901, but later on further capital had to be raised.

During 1896-7, the company had to be amalgamated and the balance restored to the right side. A dividend at the rate of 5½ per cent, absorbing £15,623, was paid out of the profits of that year. A working profit of £15,624 was made for 1907, but this has been extinguished by the provision for depreciation, so that nothing is available for dividend. A great deal of money continues to be spent in exploring the mine, and the facilities for conducting these operations are considerable. Great trial work is ongoing, and the orebodies are apt to be lean. During 1907 the total ore raised from the mine was 20,041 tons, averaging 3.68% copper. In addition to this 22,789 tons were bought, averaging 6.75%. The total ore smelted was 42,300 tons, and the production was 19,722 tons of fine copper, plus gold and silver worth £75,557. The losses in smelting were considerably higher than in previous years, but because the copper produced came from purchased ores, and as we do not know the exact terms of the purchase, it is not possible to estimate how the price of copper affects the profits. Anyhow, £4,361 was paid for the 22,789 tons of 6.75% ore, and the average price obtained for the copper sold was £85 per ton. As only one-quarter of the copper sold came from the mine, the company operates more like a smelting mill than as a copper producer. Several things require improvement yet, such as the provision of more accurate sampling apparatus, which will help to cut down the losses in smelting, and will also enable the company to purchase ore more methodically.

The report of Camp Bird, Ltd., for the year ending May 1, 1908, has been looked forward to with unusual interest on this side by shareholders and others, owing to the official and unofficial news that has been circulated recently with regard to the prospects of the mine. For some time we have been told that the veins were decreasing in value as greater depth was reached, and that J. E. Spurr has been making an examination with a view to determining the chances of discovery of workable orebodies. Mr. Spurr has completed his underground survey, and is now engaged on a surface examination. His report has not been published, and very little is said as to its nature by Mr. Beatty in his report. All we are told is that Mr. Spurr has indicated an ore-horizon below which it will not pay to go. The engineers' report shows that in all the workings the gold content is decreasing rapidly. There is one portion of the mine in the higher levels where there is a good deal of virgin ground of promising nature, and, if in future, exploring operations will be confined to this, Mr. Beatty estimates that the broken ore and the ore ready for stonping is sufficient to keep the mill going for two years or more, and to provide a mining profit of half a million pounds.

During the year 1907-8 the ore crushed was 80,057 tons dry, which yielded £1,963,583 gold, £38,315 silver, £83,315 lead, and £306 copper, being a total of £2,971,067, while the operating expenses were £685,332. Mr. Walsh took £540,853 as his share, and after allowing for a few small items, the balance of profit in London was £196,178. Out of this £161,000 has been paid as dividends, which is at the rate of 20% on the issued capital. The Company holds a large balance in hand, the amount now being carried forward being £151,453. Since the Company was formed in 1902, the total dividends have amounted to £492,000, being 11½% on the issued capital. During 1906-7, considerable sums were spent out of revenue for the purpose of re-building the mill which was destroyed by the snowslide. The metals are won from the ore by amalgamation, by concentration of sulphides, and by cyanidation. About three-quarters of the recovery is by amalgamation, 16% by concentration, and 9% by cyaniding.

The low price of tin has played havoc with the Cornish mines, and the half-yearly reports now being issued are not cheerful reading. The Dolcoath mine has made a profit of only £295 for the first half of this year, as compared with £40,000 a year ago. The total receipts were £75,500, the working costs £50,411, and the total was £47,084. The ore crushed was 48,849 tons, and the tin concentrate sold was 89 tons, which realized an average price of £5 1s. 9d., as compared with £10 11s. a ton a year ago. During the last five or six years the amount treated and the recovery have been remarkably constant, and the sole factor in profits has been the price of tin. When I wrote of Dolcoath six months ago, I mentioned that the mine was once more becoming a producer of copper. For many years the low-grade copper ores found in certain parts of the mine have been untouched, waiting for some new metallurgical discovery that would make them valuable. These ores contain 2 or 3% of copper, and from 10 to 20 lb. of black tin per ton, and they were of no use as either a tin or as a copper ore. The Elmores vacuum-plant erected last year makes a very clean separation of the pyrite, and leaves the tin untouched to go in the tailing to the dressing works. Progress with this plant has been slower than might have been expected, and as yet there is no income derived from the copper concentrate. I understand, however, that the plant is in nearly continuous operation, and that the product is being stored until such time as the situation is such that it can be made available to the tin. Some day it may be possible for tin to be paid this half year. This is good policy for two reasons: first, that no one knows how low tin is going; and, second, that additional money will be required for completing and equipping the new main shaft. The Company
is in a strong financial position, having cash and securities on hand amounting to nearly $50,000.

The Carn Brea & Thracott Mines, Ltd., has been hit hard by the fall in tin, and has made a loss of $65,000 during the period from January to June 1907. The loss during the second half of 1907 was $293. During the years 1905-1906, and the first half of 1907, the prices of tin enabled the Company to make profits. The ore treated during the six months was 31,838 tons, yielding 45.7% of tin concentrate which realized just under $90 per ton. The amount crushed, and also the yield, increased slightly over the average of the past ten years. Otherwise the losses would have been greater. In addition to tin, the Company also sold 81 tons of arsenical ore, and 4½ tons of wolfram. For some years the directors have been considering the advisability of re-organizing the workings and the plant, and it is a great pity that the opportunity was not taken a year or two ago when tin was booming. At the present time there is little or no chance of the necessary capital being obtained either in or out of the County.

MEXICO.

Monterey is unusually elated over the bright prospect for a long season of work at the steel plant in that city. Since its inception this plant has been able to work only at intervals, its capacity being considerably beyond the local demand, so that even people living in Monterey never knew whether it was running or not. On June 2 the plant was again blown in, after a long period of idleness, the accumulation of stock having been gradually disposed of in the meantime. A large order for steel rails was obtained from the Mexican National railway which it is understood will enable the plant to blast for a full six months and to operate during the whole of the contracted period. This means much to the city of Monterey. Added to the recent excellent showing in the San Pedro mines of the Mexican Lead Co., in the Diente district, near Monterey, it gives a cheerful air to all business. At Villalobos, near a horse's ride on the Mexican National railroad north from Monterey, the Minas Viejas, which were taken over a year ago by the Co. de Minas Viejas, metals, being practically the same as the Peñoles Mining Co., of Mapimi, Durango, have again been opened up as an enormously rich lead-producer, and the old workings continue to turn out their usual large tonnage of zinc carbonate ore. The Peñoles Mining Co.'s smelting plant at Mapimi has been practically re-built in the last few months under the direction of H. S. Milliken. An average of about 1000 tons per day is being smelted, and the company's own ores are such that it is forced to go into the market as an active buyer to obtain the character of ores needed for its 'mixes.' No 'cutthroat' competition is being entered into, however, as the management usually succeeds by trade to get from the other smelting companies the ores required. About eight kilometres from Mapimi, and three kilometres from Buda on the same road, is a ladle or so of finely ground silver has been made on the surface of El Suerte, and its improvement with depth, taken in conjunction with the great strength of the Mapimi veins in general, has given great encouragement to operators in this new portion of the district. At Verladera the mines and smelter of the American Smelting & Refining Co. and the American Smelters Securities Co., are said to be again running full blast, though the mines are proving to be greater producers of lead than of copper, for which latter metal the new smelting plant at Verladera was primarily intended. Some lead stocks were erected in the beginning, however, and practically all of the A. S. & R. Co.'s purchases of copper ores are going to the Aguacalientes plant. The continued low price of silver has necessitated such a curtailing of production at Indio that less than 30% of the regular number of men are now employed. The Guadalupes and Terribles are the only mines of consequence operating at Indio. Although these are gold mines, they have materially cut down production. At Mapimi the Mexican Consolidated Mining & Smelting Co., which recently purchased the Soto and Porvenir, is rapidly completing its 150-ton cyanide mill for handling both ores and old tailing. The latter will not be placed into operation for some months, and when these are cleaned up the concentrating mill is to be enlarged from an 80 to a 150 or 200-ton plant. The Boca del Cobre Mining Co. has ordered new machinery, compressors, drills, and other equipment from Denver. When erected, the work will be pushed and production materially increased. Production during development of this mine while under option paid almost half the purchase price of the property.

Guanajuato reports a weekly production of $165,000 in bullion and $95,000 in ore and concentrate, or at a rate of approximately 783,000 pesos per year at the present price of silver. The continued low market, however, is putting even these large producers on the anxious seat, and it is a question whether they will continue work if there is not prompt improvement. Three years ago, with production less than one-third what it is at present, the profits were really greater. At the Sirena mine the Guanajuato Consolidated Mining & Milling Co. has just completed the installation of a 200-kw. rotary converter of the Westinghouse Electric & Mfg. Co., from which the various mine-motors are supplied, as well as the electric locomotives that haul the ore around the mountain from the mine of La Sirena to the mill of San Francisco (La Hacienda de San Francisco de La Pastita, as it is locally known). The new equipment as it was shipped, weighed 15 tons.

BUTTE, MONTANA.

In August the Washoe smelter at Anaconda, the Butte Reduction Works, and Pittsburg smelter at Butte, turned out about 26,121,000 lb. copper, a little less than was produced in July, due to the fact that the mines were shut down for one day, and the smelter output was slightly restricted. It is noticeable that the average yield of copper per ton has been greatly reduced, and that the ore-tonnage has increased. This has been made possible by the better market for copper. The ore shipped by the different companies averages in copper about as follows: Boston & Montana Co., 76 lb. per ton; Anaconda, 62; Butte & Boston, 66; Washoe, 54; Parrot, 55; Trenon, 55; North Butte, 54; Butte Coalition, 59; Original, 90; Pittsburg & Montana, 95. To the totals of ore produced, and copper turned out, the various companies contributed as follows to the August production:

The Boston & Montana smelter at Great Falls, which has been closed for three months on account of damage by the June flood, is gradually being restored to commission, but will not be running at full capacity for several weeks. Operations have been resumed in the concentrator and reverberatory departments. Due to work still going on at some steel structures, and on a new flue in connection with
the blast-furnace department, that part of the plant has not yet been started. A force of about 700 men was necessary on the repair work during the past three months, indicating the great damage that was done to the smelter. The work consisted in re-building the walls of the head-race, removing a vast amount of earth and rock that had been deposited in the tail-race, repairing the power-house and filling in a large portion of the emitter-grounds which had been washed away.

That F. Augustus Helme is making progress in re-organizing his companies and in re-habilitating his fortunes is indicated by the reports of the re-organization plans of the Ohio Copper Co., the Bingham Co., and the Davis-Daly Estates Copper Co. It is also announced that the affairs of the latter corporation have been transferred from $4 to the concentrators, and that there will be a resumption of work at the mine and mill in the near future. Butte stockholders of the Davis-Daly Co. have received notice of a special meeting that will be held in New York for the purpose of perfecting the re-organization of that Company. The new Company is to be known as the Davis-Daly Copper Co. and will have a capital stock of 600,000 shares, 70,000 shares less than the old company. The old stock will be exchangeable for new upon payment of a $2 assessment. The new stock has a par value of $10 per share; the old was $15 par, and was underwritten at $12.50. The new stock will therefore cost the subscribers $14.50 on the old basis of subscription. The new underwriters are to get $500,000 for their services, and it is expected to raise $1,250,000 for the treasury, with which to pay off the Company’s existing debts, the obligations, and to provide a working fund which, it is hoped, will be sufficient to place the Company on a paying basis. There is mention that the vendors are to turn into the new Company some additional property not included in the old deal, but in Butte there is no information about this additional property, unless it be the Daly property on which the vendors hold unpaid options. But the title of certain old properties were supposed to be liable for the deferred payments, and the stockholders had that notion about the relations between the Company and the vendors; but it now appears that there is a substantial controversy over the question, and the vendors will make good by turning over some additional property-interests, consisting of a quarter interest in the Tintic Mining property, and in city lots. The debts of the Company aggregate about $400,000, including $300,000 in incumbrances on property, unpaid options, and about $100,000 in a floating debt. After paying all obligations, the Company expects to have a fund of about $700,000 for development work, if it is successful in collecting the $2 assessment. The old Company has already spent about $600,000 in development work and equipment. Reports of a great extent to that part of the industry. Butte mining men are much interested in the progress of the Butte & Buxton, as hundreds of claims have been located in the new district, and the results of development work are eagerly awaited. The Butte & Buxton will sink a 1000-ft. shaft, starting from an adit which is 700 ft. long. A raise will first be made to the surface, a distance of 130 feet.

The Pittsburg & New York Copper Mining Co., which owns a group of undeveloped claims south of Butte, has branched out into gold mining, and has taken over the Unatilla group of claims eight miles from Helena, which includes a small stamp-mill and cyanide plant. After a small amount of development work had been done a rich show of ore was opened at a depth of 70 ft., assays going as high as $700 per ton. Five stamps have been put to work on ore, and the cyanide plant will be started shortly. There are thousands of tons of tailing to be treated that Butte & Buxton.

That copper conditions are gradually improving, and will get much better before the close of the year, is the opinion of Horace J. Stevens. "The metal price is certain to go much higher, and, as usual, the Frenchmen and the Englishmen are making the profits," said Mr. Stevens. "They are wise enough in Europe to know when copper is cheap, and they buy it. They have a lot of cheap copper on hand there now, but not nearly so much as the copper 'bears' would have us believe. They are not selling or using that copper, but are continuing to buy at present prices to supply their needs. They will continue to do that until the price gets too high again, and then they will stop. It seems to be the case with consumers in this country that when the price of copper goes down to a point at which it can not be bought, buying stops, and when the price of copper will not be used again in large quantities. So they don't buy till prices go up, and then they purchase all the way up, and the higher the price the more copper they want. Copper will always be in demand, as it always has been, and nothing will ever take its place."

A telegram from New York announces that the option on a majority of the stock of the Butte-Montana Co. has been exercised, and that underwriters have agreed that the property will be resumed in six weeks or two months. There is no much said about Butte-Montana that very little reliance can be placed in any new announcement. The Company has always been the object of some over-zealous boosters and stock manipulators. It has a good property in the Alex Scott claim, which lies in the heart of the Butte copper producing region, and the property was not, to be taken back by the Butte & Montana Co. It is developed by a good shaft and several levels and some good ore has been opened, but not in large bodies. The troubles of the lumbermen, which threatened to involve the Amalgamated Copper Co. with the miners' union again, are in a fair way to settlement. The striking lumbermen at Hamilton and St. Regis will be taken back by the Buxton & Montana Co. The manager of the Amalgamated and lumber Interests had several long conferences with the miners and other union representatives.

SALT LAKE, UTAH.

The management of the Garfield smelter will install a battery of Dwight sintering furnaces, during the past season, a series of furnaces. The furnaces are delivered from the Utah Copper mill, and the conclusion has been arrived at that these machines will assist materially in solving some of the difficult problems presented by the fine product from the Garfield concentrator plants. It is understood, however, that the H. & H. furnaces will not be thrown out altogether, but that both systems will be utilized to advantage. Owing to the metallurgical difficulties experienced at the Garfield smelter, the plant has been taxed beyond its limit, and as I have stated in a previous letter, a state of congestion exists that was not contem-

plated a few months ago. I visited the Boston Consolidated concentrator last week and ascertained that no shipments of concentrate had been made from that source to the smelter for many weeks, and I saw a huge pile of concentrate covered with a canvas for protection from the elements, which represented a value of about $300,000. It appears that the smelter management has arranged with the Boston company to withhold the mill-product for the time being, but in the meantime is making substantial cash advances on it. The best evidence that I found of this was a sign posted up in a conspicuous place indicating that the concentrate belonged to the American Smelting & Refining Co. Hence, it is quite immaterial to the Boston Consolidated whether the product of its mill is moved over to the smelter now, or at some future time.
